Re: Remedial Investigation Report
Former Equity Works MGP
Brooklyn, Kings County
Site # 224050

Dear Mr. Ryan:

The Department of Environmental Conservation (Department) and the New York State Department of Health (NYSDOH) have reviewed the Remedial Investigation Report for the subject site. The report is acceptable and is hereby approved.

The next appropriate step is to begin the Feasibility Study (FS) to evaluate remedial options for the site. I recommend that a Feasibility Study scoping meeting be held among the Department, National Grid and NYSDOH to determine the appropriate scope for the FS. Please provide dates in September and early October when you and your team can be available to meet in our Albany offices. I will then coordinate with NYSDOH to set a meeting time.

Yours truly,

Henry T. Willems
Engineering Geologist 2

Executive Summary

On behalf of the Brooklyn Union Gas Company (BUG) (dba National Grid NY), AECOM Environment (AECOM) has conducted a Remedial Investigation (RI) of the former Equity Works manufactured gas plant (MGP) Site (the Site) and prepared this RI Report to present the results.

The former MGP facility was constructed in 1892 by the Equity Gas Works Construction Company. The MGP facility was acquired by BUG, a predecessor company to National Grid, in approximately 1903. The plant was developed to its maximum extent in1921. The relief holder was partially decommissioned by 1931 and the gas manufacturing equipment removed by 1933. Throughout this report, the area comprising the footprint of the historic MGP is defined as the "Site." Collectively, the Site and other off-Site areas investigated as part of the RI are referred to as the "RI Study Area."

The entire Site is now owned by third parties. The manufacturing and industrial operations in the Site area prior to and during this period included companies that processed/stored oil, manufactured rope/twine, and dyed fabric. These operations are believed to have resulted in a complex nature of environmental impacts to soil and groundwater that included petroleum/tar, solvents and dyes.

Site Setting

The former MGP facility was located on three parcels of land at 222 – 254 Maspeth Avenue, Brooklyn, Kings County, New York 11211, northwest of the English Kills tributary of Newtown Creek, between Grand Street and the Brooklyn Queens Expressway (Highway 278).

The Site is currently occupied by Cooper Tank Recycling Company and is zoned for heavy manufacturing use. Current operations at the Site include recycling and sorting of building materials. Currently, the Site is bounded by the following industrial or commercial facilities/areas:

- To the north – Maspeth Avenue and National Grid's Greenpoint Energy Center Site which includes a liquefied natural gas (LNG) facility. A separate MGP operated on the property from 1927 to approximately 1952.
- To the south – The adjacent property was initially a marsh with drainage running to the south to the English Kills tributary of Newtown Creek. The property was filled in the early 1900s and subsequent operations on the property included coal transfer and storage, storage for building materials, fuel oil storage and truck filling, carpet handling, material recycling, and industrial manufacturing and shipping. More recent operations in the property include electronics storage and shipping and paper products storage and shipping.
- To the east –The 300 Maspeth Avenue property initially consisted of marsh and drainage canals, which were progressively filled over time. The southern portion of the property was filled in the early 1900s, while the northern portion of the property was not developed until the early 1960s. Operations subsequent to the filling included coal yards, lumber yards, oil handling, oil and putty manufacturing, fuel oil storage and truck filling, and motor freight with truck servicing. Facilities have included multiple above ground petroleum storage tanks as well as six 10,000 gallon underground storage tanks (USTs) for gasoline. The latter were likely removed when the property was developed as a truck terminal and parking lot in the mid-1960's. The truck terminal is currently occupied by Federal Express.

- To the west – Vandervoort Avenue, and a consistent set of businesses, including a shipping warehouse and a truck wash facility, have occupied the adjacent properties. Current operations include a truck wash facility, metal and glass fabrication, and retail businesses.

Many of the industrial operations that operated in the area of the Site used petroleum feedstocks or managed products that are similar to those generally associated with the MGP process. As a result, these non-MGP operations may be associated with environmental residuals that are similar in nature and composition to by- products from the MGP process and can complicate the process of identifying specific sources of impact.

Remedial Investigation

The RI was performed pursuant to a Multi-Site Order on Consent and Administrative Settlement, Index #A2-0552-0606, executed on February 22, 2007 and modified on August 10, 2007, between BUG (now d/b/a National Grid NY) and the New York State Department of Environmental Conservation (NYSDEC). The RI was performed to identify sources of environmental impacts, delineate the associated extent of impacts, determine the surface and subsurface conditions in the area of the Site, and evaluate potential off-Site migration pathways and their potential contributions to media and receptors. The fieldwork for the RI was performed with NYSDEC oversight using procedures described in the NYSDEC-approved documents, including: a Remedial Investigation Work Plan and four addenda, a Field Sampling and Analytical Plan (FSAP), a Quality Assurance Project Plan (QAPP), a Community Air Monitoring Plan (CAMP), and a Site-Specific Health and Safety Plan (HASP).

The data presented in this RI Report were collected over six separate mobilizations during the period from September 2009 to May 2015, with the completion of the following activities:

- Drilling of 93 soil borings and 4 test pits, with the collection of 148 subsurface soil samples for analysis
- Collection of 4 surface soil samples for analysis
- Installation of 40 monitoring wells and collection of 40 groundwater samples (including 2 groundwater grab samples) for analysis

Additional activities included the evaluation of potential for vapor intrusion, and aquifer testing and tidal monitoring at selected monitoring wells.

During the RI, two Interim Remedial Measures were performed at the Site. The first, completed in September of 2012, removed shallow soils containing visible source material in a portion of the 254 Maspeth Avenue parcel where construction work was planned by the current property owner. In April 2013, 23 recovery wells were installed within and along the perimeter of the Site to recover non-aqueous phase liquid (NAPL) present above a subsurface confining layer.

Summary of Findings

A discussion of the geology/hydrogeology and summaries of the characterization of impacts to soil and groundwater are provided below.

Geology and Hydrogeology

The stratigraphy in the RI Study Area includes urban fill (to a depth of 15 to 25 feet below ground surface (ft bgs) that is generally underlain by the following low permeability units:

- a meadow mat (the former ground surface prior to development), encountered from 8 to 26 ft bgs, that was laterally continuous beneath the RI Study Area.
- an intermediate clay unit, encountered from 36 to 52 ft bgs, that was laterally continuous under the majority of the RI Study Area with the exception of the western portion of the Site.
- a lower clay unit, encountered from 78 to 86 ft bgs, comprised of a discontinuous clay unit observed in a subset of borings beneath the 222, 252, and western portion of the 254 Maspeth Avenue parcels, and extending to the north onto the Greenpoint property and to the south beneath 1 Rewe Street and the western portion of 7-9 Rewe Street.
- the regional Gardiners Clay unit, that was laterally continuous beneath the RI Study Area and located from 80 to 100 ft bgs. .

Interbedded sands and silts are present beneath the meadow mat and between the various low permeability units. As noted above, the intermediate clay and lower clay units were observed to pinch out towards the western edge of the Site near the former relief holder.

The water table was observed at 6 to 10 ft below ground surface. Groundwater flow in the shallow, intermediate and deep overburden aquifer zones is generally to the east and southeast. On a regional basis, given that the Upper Glacial Aquifer (UGA) beneath the site is over 100 feet (ft) thick and that the English Kills represents the upper reach of an estuarine system of Newtown Creek, it is likely that some portion of deep groundwater flow beneath the Site underflows the English Kills/Newtown Creek system and discharges more directly to the regional East River discharge boundary. Although there are measurable vertical head potential differences between the aquifer zones from shallow to intermediate and from deep to intermediate portions of the aquifer, the presence of the low conductivity meadow mat and intermediate clay units likely impedes actual groundwater flow between the shallow to intermediate and deep to intermediate zones. The data collected during the project indicates that portions of the deep aquifer beneath the RI Study Area can be affected by tidal cycles.

Non Aqueous Phase Liquid (NAPL) and Soil Impacts

NAPL impacts do not extend beyond the RI Study Area and are largely confined to the Site. The evaluation of soil quality was complicated by the fact that impacts, including staining, sheen and the presence of NAPL can be evidence of environmental impacts from the MGP as well as from a number of the other non-MGP industrial sources that have been identified in the RI Study Area. However, based on Site history and RI findings, tar handling structures on the 222 Maspeth Avenue parcel and the western edge of the 254 Maspeth Avenue parcel were identified as the likely sources of both NAPL and dissolved phase chemicals in the groundwater at the Site. Non-MGP related constituents such as polychlorinated biphenyls (PCBs) were also identified in soils beneath the RI Study Area.

NAPL is believed to have migrated vertically downward through the fill under density driven flow until it reached the former natural ground surface (meadow mat), where a portion of the NAPL spread laterally to the north and east within, or on top of, the meadow mat surface. NAPL also migrated vertically through the underlying more permeable glacial outwash sands, where it collected on the intermediate clay layer at typical depths of 45 to 50 ft bgs. The intermediate clay unit pinches out

under the 222 Maspeth Avenue parcel roughly mid-way beneath the former No. 1 Relief Holder and is absent in borings advanced west of this area.

The absence of the confining intermediate clay at the western edge of the Site allowed portions of the released NAPL to migrate vertically downward to the next confining or semi-confining layer, which is identified in this RI as the lower clay lens. The lower clay lens is a discontinuous clay unit observed in a subset of borings beneath the 222, 252, and western portion of the 254 Maspeth Avenue parcels, and extending to the north onto the Greenpoint property and to the south beneath 1 Rewe Street and the western portion of 7-9 Rewe Street. The lower clay lens is absent in the western portion of the 222 Maspeth Avenue parcel.

The absence of the lower clay lens beneath a portion of the 222 Maspeth Avenue parcel may have allowed some of the released NAPL to migrate vertically downward to the top of the Gardiners Clay. As the NAPL continued to migrate further from its source, the volume of the NAPL and the driving head of the NAPL decreased. As a result, the least amount of NAPL was observed at the top of the Gardiners Clay surface. Where present, NAPL presence also aligned with the topography of the top of the Gardiners Clay surface.

NAPL presence was observed to be aligned with the topography of the various lower permeability units, which largely limited its potential to migrate from the Site to adjacent locations within the RI Study Area. Data from the RI demonstrated that although NAPL impacts were observed in one boring on the eastern edge of the RI Study Area on the FedEx property, the limited impacts were in a residual rather than saturated state, demonstrating no potential for future migration. NAPL impacts were observed under the properties immediately adjacent to the Site to the south.

The laboratory analysis of soil samples demonstrated that exceedances of the applicable NYSDEC Soil Cleanup Objectives (SCOs) were largely limited to volatile organic compounds such as benzene, toluene, ethylbenzene and xylenes (BTEX) and polycyclic aromatic hydrocarbons (PAHs). Both classes of compounds are associated with petroleum and MGP residuals. There were limited detections of polychlorinated biphenyl compounds, and none of the detections were associated with the MGP operations. Twelve of the 15 samples with detections of PCBs above the Unrestricted Use SCOs were from the top 6.5 ft of the surface material of the Site in fill placed following cessation of MGP operations. The remaining samples with detections of PCBs above Unrestricted use SCOs were collected at an offsite location (300 Maspeth Avenue) where MGP operations did not occur.

The horizontal extent of BTEX and PAH impacts in soil was delineated by borings to the west along Vandervoort Avenue, to the south on adjacent commercial properties, to the east (with the exception of an area on the FedEx property (300 Maspeth Avenue) where USTs were formerly located), and to the north, onto National Grid's Greenpoint Energy Center which is currently being investigated under a separate RI under NYSDEC oversight.

The vertical delineation of BTEX and PAH impacts in soil is limited to the RI Study Area and only 19 of 55 samples taken from depths below 40 ft bgs or greater had constituent concentrations above the Unrestricted Use SCOs. It's important to note that the nature and extent of environmental impacts is affected by a number of factors including historic land use and the contribution from surrounding sources.

Groundwater

Dissolved phase impacts in shallow zone (water table) wells are largely isolated to the former Site boundary, with significantly lower levels (typically low to non-detect) at adjacent locations in the RI Study Area.

Constituent concentrations in the intermediate portion of the overburden aquifer are generally the highest observed in the RI Study Area, consistent with this zone containing the most widespread presence of NAPL. Dissolved BTEX and PAHs were highest at on-Site wells and decreasing in the direction of groundwater flow at adjacent locations in the RI Study Area. No PCBs were detected in groundwater from any of the wells sampled. Given the trends observed in the data, dissolved phase concentrations of these constituents will decrease further at locations outside of the RI Study area due to biodegradation, attenuation, and dilution. Non-MGP related constituents such as chlorinated volatile organic compounds (cVOCs) are also present in groundwater beneath the RI Study Area.

Dissolved phase impacts in the deepest portion of the overburden aquifer above the Gardiners Clay are lower in concentration and generally consistent laterally with the overlying intermediate zone. As indicated previously, source material in the RI Study Area may originate from a number of sources with similar characteristics. As a result, the dissolved phase impacts may be associated with commingled sources. The potential for commingled impacts is supported by the presence of constituents, such as chlorinated solvents, which were not in use during the period of operation of the MGP.

Qualitative Human Health Exposure Assessment

The results from the RI are appropriate to assess the potential for exposure to constituents present in impacted soils, groundwater, soil vapor, and indoor air. Under current conditions, complete exposure pathways for potential receptors in the RI Study Area do not exist because of the current use and activities of the properties. A potential for indoor air pathway at an on-Site location was addressed by an interim action to control a preferential pathway at a utility access structure, and constituents detected at other locations within the RI Study Area were determined to either be consistent with ambient background or not attributed to vapor intrusion. Shallow soils containing visible source material were also removed from the Site under an Interim Remedial Measure (IRM) completed in September 2012.

Future construction workers who perform excavation work in areas on or adjacent to the Site may potentially be exposed to impacts in subsurface soil and groundwater. Note that New York City provides potable water to Brooklyn, and potential exposure related to the consumption of groundwater is not a concern. The potential construction worker pathway on-site is currently addressed by an Interim Site Management Plan that prohibits subsurface work without the use of OSHA-trained personnel, a site-specific HASP, and coordination with National Grid's SIR Department.

Fish and Wildlife Resources Impact Analysis

An assessment of Site conditions against the Fish and Wildlife Resources Impact Analysis (FWRIA) Decision Key determined that an FWRIA was not required.

Conclusions

The objectives of the RI have been fulfilled and the nature and extent of environmental impacts at the RI Study Area have been adequately defined. The extent of NAPL is defined vertically and horizontally

within the RI Study Area. The RI demonstrated that there is no migration of NAPL beyond the RI Study Area. Where present at one boring on the eastern edge of the RI Study Area, the NAPL was documented in a residual state and not mobile. NAPL is largely contained within the Site itself by the topography of the various subsurface low permeability confining layers. National Grid is currently conducting an IRM to recover NAPL from recovery wells screened at and above the intermediate clay layer beneath the Site. The NAPL above the intermediate clay layer and other depths was determined to be stable prior to implementation of the IRM as evidenced by the documented decrease in NAPL impacts away from source areas showing a progressive change from NAPL saturation to NAPL coating to staining and odors and at distal areas within the RI Study Area. The extent of subsurface soil impacts primarily associated with BTEX and PAHs, are also generally delineated within these same areas.

Dissolved phase groundwater impacts, including BTEX and a limited set of PAHs are characterized within the RI Study Area and concentrations are lower at downgradient wells compared to the Site. The dissolved-phase impacts are the result of a number of factors including geologic conditions, groundwater flow patterns, and the presence of source material in soil. The source material in the RI Study Area may originate from a number of sources with similar characteristics. As a result, the dissolved phase impacts may be associated with commingled sources. Given the trends observed in the data, the dissolved phase concentrations of these constituents will decrease further at locations outside of the RI Study area due to biodegradation, attenuation, and dilution.

Complete exposure pathways have not been identified for potential receptors in the RI Study Area given the current use of the properties. Potable water in the RI Study Area is provided by the City of New York, and areas containing environmental impacts are covered by asphalt or developed property and therefore do not pose an immediate risk to receptors. However, future construction workers who may perform excavation work in areas on or adjacent to the Site may potentially be exposed to impacts in subsurface soil and groundwater. The potential construction worker pathway on-site is addressed by an Interim Site Management Plan that prohibits subsurface work without the use of OSHA-trained personnel, a site-specific HASP, and coordination with National Grid’s SIR Department.

1.0 Introduction

On behalf of the Brooklyn Union Gas Company (BUG) (dba National Grid NY), AECOM Environment (AECOM) has conducted a Remedial Investigation (RI) of the former Equity Works manufactured gas plant (MGP) Site (the Site), and prepared this RI Report to present the results. The former MGP was located at 222-254 Maspeth Avenue in Brooklyn, Kings County, New York (Figure 1-1). The area comprising the footprint of the historic MGP evaluated during this RI is defined as the "Site." Collectively, the Site and other off-Site areas investigated as part of the RI are referred to as the "RI Study Area."

The MGP facility was constructed in 1892 by the Equity Gas Works Construction Company. The MGP facility was acquired by BUG, a predecessor company to National Grid, in approximately 1903, operated until 1929, and was decommissioned by 1933 with all plant structures removed with the exception of former purifying house and generator house buildings that were listed as vacant on the 1933 Sanborn map. The entire Site is now owned by third parties: 222 Maspeth Avenue is owned by 222 Maspeth Avenue Inc., 252 Maspeth Avenue is owned by 252 Maspeth Avenue LLC, and 254 Maspeth Avenue is owned by 254 Maspeth Avenue LLC. The Site currently houses a waste recycling facility and associated vehicle and equipment storage operated by Cooper Tank Recycling, with primary activities occurring at the 222 Maspeth Avenue parcel. The RI Study Area is located in a highly industrialized area of Brooklyn. The historic and current manufacturing and industrial operations results in a complex nature of environmental impacts to soil and groundwater.

The RI was performed pursuant to a Multi-Site Order on Consent and Administrative Settlement, Index #A2-0552-0606, executed on February 22, 2007 and modified on August 10, 2007, between The Brooklyn Union Gas Company (now d/b/a National Grid NY) and the New York State Department of Environmental Conservation (NYSDEC). The field investigation was designed to identify sources of environmental impacts, delineate the associated extent of impacts, determine the surface and subsurface conditions of the RI Study Area, and evaluate potential off-Site migration pathways, potential off-Site contributions to the RI Study Area, and human receptors in the RI Study Area.

The fieldwork for the RI was performed in accordance with NYSDEC oversight using procedures described in the NYSDEC-approved *Remedial Investigation Work Plan, Equity Former MGP Site, Brooklyn, New York, NYSDEC Site No.: 224050, Order on Consent Index #: A2-0552-0606* (RIWP) dated July 2009 (AECOM, 2009). Four companion documents were prepared to detail additional procedures and protocols for the RI and were included as Appendices C through F to the RIWP. Appendix C, Field Sampling and Analytical Plan (FSAP), specified the field sampling procedures. Appendix D, Quality Assurance Project Plan (QAPP), specified the field and laboratory quality assurance/quality control procedures. Appendix E, Community Air Monitoring Plan (CAMP), provided procedures to be used for the monitoring of potential fugitive emissions generated during the invasive sampling tasks conducted during the investigation. Appendix F, Site-Specific Health and Safety Plan (HASP), was developed to provide information and procedures to protect AECOM personnel and to make other on-Site personnel aware of known or suspected health and safety hazards.

There were four RIWP Addenda (No. 1 through No. 4) that were generated to investigate the subsurface conditions within the RI Study Area. These addenda are:

- Remedial Investigation Work Plan Addendum (No. 1) – to further delineate environmental impacts identified during the initial RI work (National Grid, 2011b)
- Remedial Investigation Work Plan Addendum (No. 2) – to further delineate environmental impacts off-Site to the north and east, and advance of a deep soil boring to identify the elevation of the Jameco Gravel and assess potential impacts (National Grid, 2012a)
- Remedial Investigation Work Plan Addendum (No. 2) Modification – to further delineate the downgradient extent of dissolved phase constituents to the east of the Site (National Grid, 2013a)
- Remedial Investigation Work Plan Addendum (No. 3) – to investigate former tidal channels at the 300 Maspeth Avenue property and determine the presence or absence of environmental impacts (National Grid, 2013b)
- Remedial Investigation Work Plan Addendum (No. 4) – to investigate subsurface conditions to the south of the Site beneath current buildings located at 1 and 7-9 Rewe Street (National Grid, 2015)

In addition, two Pre-Design Investigations (PDIs) were conducted in the RI Study Area that provided additional data that is used in this RI Report:

- PDI Work Plan for Shallow Soil Removal – to delineate the extent of visually contaminated soils on the 254 Maspeth Ave parcel and pre-characterize soil for disposal options ahead of earth work planned by the property owner; addendum to work plan added test pits on 252 Maspeth Ave parcel (National Grid, 2011a; National Grid, 2011c).
- PDI Work Plan for Potential Barrier Wall Design – to gather geotechnical information for design of a possible barrier wall at the 252-254 Maspeth Ave parcels; addendum to work plan added installation of wells to evaluate potential for NAPL recovery (National Grid, 2012b; National Grid, 2012c).

1.1 Remediation Investigation Objectives

Based on the operational history of the former Equity Works MGP facility between approximately 1892 and 1929, the objectives of the RI were to:

- Evaluate the nature and extent of environmental impacts in the RI Study Area in accordance with NYSDEC DER-10 Technical Guidance for Site Investigation and Remediation (NYSDEC, 2010). Specifically, develop the conceptual site model (CSM) that explains the nature and extent and assesses the potential risk to human or ecological receptors from potential impacts.
- Perform a vapor intrusion study in accordance with New York State Department of Health (NYSDOH) Guidance for Evaluating Soil Vapor Intrusion in the State of New York (NYSDOH, 2006).
- Conduct a Qualitative Human Health Exposure Assessment (QHHEA).
- Develop the dataset necessary to allow preparation of a Feasibility Study (FS) to evaluate remedial alternatives that will reduce and/or eliminate routes of exposure and the threat to public health or the environment posed by impacts associated with the Site. The Feasibility Study shall be prepared in a manner consistent with NYSDEC DER-10 Technical Guidance for Site Investigation and Remediation (NYSDEC, 2010).

1.2 Scope of Work

The scope of work for the RI, as defined in the NYSDEC-approved Work Plans, RI Addendums, and subsequent correspondence, includes:

- Pre-investigation coordination/meetings to facilitate implementation of the RI
- Locating underground utilities in the investigation areas
- Community air monitoring during invasive drilling and test pitting activities
- Surface soil sampling and analysis
- Advancement of soil borings and collection of subsurface soil samples for analysis
- Advancement of test pits and collection of subsurface soil samples for analysis
- Monitoring well installation and development
- Groundwater sampling
- Aquifer slug testing at select well locations
- Groundwater elevation gauging and tidal monitoring during various tidal cycles within the nearby English Kills tributary of Newtown Creek
- Performance of a vapor intrusion study at two buildings located within the Site and three buildings adjacent to the Site to the south
- Surveying of all new sampling points, wells, and borings
- Investigation residuals management

The data presented in this RI Report were collected over several mobilizations performed during:

- September through December 2009 – Completed initial RI scope of work
- March and August 2010, February 2011 – Completed additional vapor intrusion sampling at 222 and 252 Maspeth Ave
- September through November 2011– Completed RI Addendum No. 1 scope of work and PDI for Shallow Soil Removal
- July through August 2012 – Started RI Addendum No. 2 scope of work and PDI for Potential Barrier Wall Design
- January through February 2013 - Completed RI Addendum No. 2 scope of work
- May 2014 and October 2014 - Completed RI Addendum No. 3 scope of work
- March through May 2015 - Completed RI Addendum No. 4 scope of work

1.3 Report Organization

This RI Report is organized into nine sections following this introduction.

- Section 2 describes the RI Study Area and adjacent areas, and presents historical ownership and operational summary information.

- Section 3 describes the National Grid field investigation activities performed in the RI Study Area.
- Section 4 summarizes information regarding the RI Study Area topography, geology, hydrogeology, and the observed extent environmental impacts.
- Section 5 summarizes the results of the laboratory analyses for environmental media sampled during the investigation.
- Section 6 provides a summary of the fate and transport of visible and analytical impacts in the RI Study Area.
- Section 7 summarized remedial work already completed in the RI Study Area.
- Section 8 presents a qualitative human health exposure assessment for the RI Study Area.
- Section 9 presents an evaluation of potential impacts to fish and wildlife resources in the RI study area.
- Section 10 presents the conceptual site model.
- Section 11 presents a summary and conclusion related to the RI work.
- Section 12 presents recommendations for additional actions.
- Section 13 provides a list of references cited in this report.

Tables and figures are included in sections that immediately follow the report text.

Appendices to this RI Report include the following:

- Appendix A Historical Atlas Reports for the City of Brooklyn from 1886 to present
- Appendix B Summary of Historical Data - Includes a summary of documents reviewed (Table B-1), Sanborn maps, previous soil boring and monitoring well logs, historical Brooklyn Union Gas Company (BUG) drawings, historical Site photographs, historical newspaper articles.
- Appendix C Dust Suppression Well Information
- Appendix D Soil Boring Logs and Well Construction Logs (Current and Historical)
- Appendix E Test Pit Excavation Logs
- Appendix F Well Development Logs
- Appendix G Groundwater Collection Records
- Appendix H Slug Testing Data Analysis
- Appendix I Community Air Monitoring Program Records
- Appendix J Indoor Air Survey Forms
- Appendix K NYSDEC Analytical Services Protocol Category B Deliverable Data (CD-ROM)
- Appendix L Data Usability Summary Reports (CD-ROM)
- Appendix M Photo Log of Floor Slab Penetration Caulking Work, Cooper Tank Locker Room Area
- Appendix N IRM Completion Reports (CD-ROM)

2.0 RI Study Area Description and History

This section presents a description of the RI Study Area, information regarding Site ownership and operational history, and the results of previous investigations and remedial work performed. A summary of the documents reviewed, including historical photographs, historical topographic maps, historical drawings, Sanborn maps, and aerial photographs for these and other local properties, is provided in Table 2-1.

2.1 Site Description

The former Equity Works MGP facility was historically located at 222 – 254 Maspeth Avenue, Brooklyn, Kings County, New York 11211, northwest of the English Kills tributary of Newtown Creek, between Grand Street and the Brooklyn Queens Expressway (Highway 278). Figure 2-1 shows the Site location and surrounding properties. Current zoning and land use at the Site is heavy manufacturing, with the entire Site being occupied by Cooper Tank Recycling Company. Current operations at the Site include recycling and sorting of building materials. Current zoning and land use in areas adjacent to the Site include a mixture of commercial and industrial uses (see Figure 2-2). The Site is comprised of the following three parcels of land:

Block/Lot Number	Owner's Name and Address	Operator's Name and Address	Status
Block 2927 Lot 44	222 Maspeth Avenue Inc.	222 Maspeth Avenue Brooklyn, NY 11215	Lot used as an active waste recycling/ waste transfer station. Currently one enclosed building housing offices and one open building (no walls, with roof) housing waste recycling operations are present on the lot. The lot is operated by Cooper Tank Recycling Co.
Block 2927 Lot 54	252 Maspeth Avenue LLC	252 Maspeth Avenue Brooklyn, NY 11215	Currently one building is located on the lot (approximately 2,500 square feet [ft]). Used as a maintenance center for equipment. Currently leased by Cooper Tank Recycling Co.
Block 2927 Lot 57	254 Maspeth Ave, LLC	254 Maspeth Avenue Brooklyn, NY 11215	Currently a parking area with truck scales used for occasional storage of empty roll-offs and vehicle parking for Cooper Tank personnel working at 222 Maspeth Avenue.

Figures 2-1 and 2-2 provide maps showing the locations of the parcels listed above and showing adjacent parcels in the Site area.

As demonstrated by the following discussions of historic and current site use of properties within the RI Study area, many of the industrial operations used feedstocks or managed products that are similar to those generally associated with the MGP process. As a result, these non-MGP operations may be associated with environmental impacts that have characteristics that are similar in nature and

composition to by- products from MGP sites. The potential commingling of environmental impacts from these non-MGP operations such as staining, sheen and NAPL may complicate the determination of a definitive source of impacts in some portions of the RI Study Area.

2.2 Adjacent/Off-Site Properties

Currently, the Site is bounded by the following industrial or commercial facilities/areas.

- To the north - Maspeth Avenue and other National Grid properties (the Gate Station at 285 Maspeth Ave. and the Greenpoint Energy Center at 287 Maspeth Ave.) that were part of a separate former MGP.
- To the south – Industrial/commercial properties abuts the Site at 1 Rewe Street and 7-9 Rewe Street. They have been occupied by a relatively consistent set of businesses, including a paper company and warehouse since approximately 1965.
- To the east – A Federal Express (FedEx) truck terminal and parking lot at 300 Maspeth Avenue that has been operated by various parties since the mid-1960's.
- To the west – A portion of the 1 Rewe Street building and Vandervoort Ave borders the Site to the west. A consistent set of businesses have occupied the adjacent properties to the west across Vandervoort Ave., including the Brooklyn Truck Wash facility located at 184 Maspeth Avenue.

The locations of these properties are also generally illustrated on Figure 2-1, with a summary of their historical use presented in Table 2-2. A summary of environmental database search records for the properties/areas adjacent to the Site is presented in Table 2-3. As indicated, significant off-Site impacts identified to date with the potential to affect the Site include petroleum releases at the truck terminal (to the east) and oil that has been observed on several occasions in the streets to the west of the Site in the area of the Vandervoort and Maspeth Avenue intersection. In May 2007, when replacing utility poles in the intersection of Maspeth and Vandervoort Avenues, oil was reported to be found in the soil, but no source was identified (Spill No. 0701343, DEC memo 205635, closed June 28, 2007; and Spill No. 0701344, DEC memo 205638, closed June 28, 2007). In August 2007, a sheen was observed bubbling from the bottom of an excavation at this intersection (Spill No. 0705958; DEC memo 207726, closed November 17, 2008).

2.3 Current Site Topography and Drainage

The ground surface in the area of the former MGP operations is approximately 14 ft above mean sea level. The topography at the Site and in the RI Study Area is level. The English Kills tributary of Newtown Creek is located approximately 700 ft southeast of the Site. Surface drainage generally follows surface topography, and is managed through an on-Site storm water drainage system that drains to Maspeth Avenue. Within the 222 Maspeth Avenue parcel and the 254 Maspeth Avenue parcels, the ground surface is covered with up to one foot of concrete to limit surface water infiltration and facilitate work activities (better traction and ability to scrape waste debris). The ground surface at the 252 Maspeth Avenue parcel is mixture of concrete and compacted soil/stone.

2.4 Regional Geology and Hydrogeology

According to P.E. Misut and Jack Monti Jr.'s, 1999 article, "Simulation of ground-water flow and pumpage in Kings and Queens Counties, Long Island, New York," in the U.S. Geological Survey Water-Resources Investigations Report 98-4071, the bedrock throughout the region consists of

undifferentiated gneiss, schist, and pegmatite. The crystalline bedrock exhibits a soft, clayey, weathered zone up to 100 ft thick. The bedrock is relatively impermeable, with water transmitted along faults and fractures.

According to Herbert Buxton and Peter K. Shernoff's 1999 article, "Ground-Water Resources of Kings and Queens Counties, Long Island, New York," United States Geological Survey, Water Supply Paper 2498, the Lloyd Sand Member of the Raritan Formation, which acts as an aquifer, overlies bedrock beneath the RI Study Area and consists mainly of deltaic deposits of fine to coarse quartzose sand interbedded with gravel, clay and silt. The unit ranges from 0-300 ft thick and from 90-825 ft below sea level. The Lloyd Sand Member yields up to 2000 gpm (gallons per minute) in some wells. Specific capacities are as high as 44 gpm per foot of drawdown. Water within the aquifer is often under artesian pressure and the horizontal hydraulic conductivity is reported to be in the range of 33-75 ft/d (ft per day) (Misut and Monti, 1999).

The Clay Member of the Raritan Formation, which acts as a confining unit, overlies the Lloyd Sand Member and consists of gray, white, red or purple deltaic clay and silty clay and some interbedded layers of sand and gravel. The unit ranges from 0-200 ft thick and from 30-650 ft below sea level (Buxton and Shernoff, 1999). The Clay Member is an impermeable confining unit. Local lenses and layers of sand and gravel with moderate to high permeability are encountered in some areas. The vertical hydraulic conductivity is 0.001 ft/d (Misut and Monti, 1999).

The Jameco Gravel, which acts as an aquifer, overlies the Clay Member of the Raritan Formation and consists of coarse sand and gravel with some cobbles and boulders consisting of dark brown and dark gray igneous, metamorphic, and sedimentary rocks. The n it ranges from 0-200 ft thick and from 90-240 ft below sea level (Buxton and Shernoff, 1999). The Jameco Gravel is highly permeable and may yield as much as 1500 gpm. Specific capacities are as high as 135 gpm per foot of drawdown. Water is often under artesian pressure and the horizontal hydraulic conductivity is reported to be in the range of 200-300 ft/d (ft per day) (Misut and Monti, 1999).

The Gardiner's Clay, which acts as a confining unit, overlies the Jameco Gravel and is comprised of a greenish-gray clay and silt with some interbedded sand and gravel. The unit ranges from 0-150 ft thick and from 40-200 ft below sea level (Buxton and Shernoff, 1999). The Gardiner's Clay is the principal confining unit in the region. Locally, the Gardiner's Clay may contain moderately to highly permeable sand and gravel lenses. The vertical hydraulic conductivity ranges from 0.001-0.0029 ft/d (Misut and Monti, 1999).

The Upper Pleistocene glacial deposits, which overlie the Gardiner's Clay and act as an aquifer, include terminal moraine deposits, ground moraine deposits, and glacial outwash deposits consisting of clay, sand, gravel and boulders. The unit ranges from 0-300 ft thick (Buxton and Shernoff, 1999). The hydrogeologic properties of the Upper Pleistocene glacial deposits (upper glacial aquifer) are highly variable. The till is poorly permeable, the sand and gravel part of the outwash is highly permeable. Yields of individual wells are as much as 1,700 gpm. Specific capacities of wells are as much as 109 gpm per foot of drawdown and the horizontal hydraulic conductivity ranges from 20-80 ft/d in the moraines to 200-300 ft/d in the outwash (Misut and Monti, 1999).

The recent Holocene deposits are grouped with the upper glacial aquifer and consist of tan to white beach sand and gravel, dune sand and gray bay bottom silt and clay deposits. The beach and dune deposits are well stratified and well sorted. The recent deposits also contain fill made up of earth, rocks, concrete fragments, ash, rubbish and hydraulic fill (Misut and Monti, 1999). The sandy beds of

the Holocene deposits have moderate to high permeability beneath barrier beaches (Misut and Monti, 1999).

2.5 Pre-MGP Site History

A 1776 survey of Newtown Creek shows that the area surrounding the creek was a mixture of tidal channels and marshland that extended to the west to approximately the current location of Vandervoort Avenue prior to development of the RI Study Area. A figure showing the area of the former MGP prior to development is shown on Figure 2-3. Prior to the mid-1800s, the creek and its tributaries were used for agriculture and commerce transport. In 1854, the country's first kerosene refinery was constructed along Newtown Creek and by 1870 over 50 petroleum refineries were located along the creek (NYSDEC, http://nysdecgreenpoint.com/ProjectHistory.aspx). By the 1880s the Creek and its tributaries were constructed to their current configuration. In circa 1880 to 1900, channel improvements and land side improvements supported an expansion of industrialization along the Creek and by 1900 most of Newtown Creek contained bulkheads (NYSDOT, 2005).

Historical Atlas Reports for the City of Brooklyn were also reviewed from 1886 prior to MGP construction. Businesses that were in operation close to or adjacent to the Site prior to the operation of the MGP included the Lawrence Rope Works that formerly included a tar house in the location of the current Brooklyn Truck Wash property (184 Maspeth Avenue) that operated from 1886-1893 and the Bushwick Chemical Works, located at the intersection of Vandervoort Avenue and Metropolitan Avenues, that operated from 1886-1899 (Appendix A).

2.6 MGP Site History

The following sections summarize the Site history and usage based on a review of Sanborn maps covering a 107 year period from 1888 through 1995, aerial photographs, historical survey maps, historical BUG drawings, and historical photographs. A summary of the historical information is provided in Table 2-4.

A review of the Site history has been developed based on a review of the historic Sanborn Fire Insurance maps, aerial photographs for the Site as well as other available information including internal BUG plant facility plans and municipal records. A copy of the maps and aerial photos is included in Appendix B, with a summary of the pertinent historical information for the property provided in Table 2-4. Figure 2-4 shows the locations of former MGP structures and other historical Site features.

The MGP facility was constructed in 1892 by the Equity Gas Works Construction Company. It operated from 1893 to 1929. BUG acquired the MGP in approximately 1903. The MGP is first evident on 1903 and 1905 BUG facility maps with gas generation, gas storage (430,000 cu. ft relief holder), and cleaning (purifier house) equipment/processes in place. Support facilities included coal storage/delivery facilities and miscellaneous tar and oil storage capacity, including tar wells, tar separators, drip tanks, and gas oil tanks.

The 1907 Sanborn map shows a consistent, although slightly more extensive, plant layout. The plant appears to be developed to its maximum extent on a 1921 BUG facility plan, although largely maintaining the layout shown on the earlier 1903 and 1905 plans. A 1932 BUG plan indicates that the relief holder was partially decommissioned and the 1933 Sanborn map shows that the gas manufacturing equipment had been removed with the former purifying house and generator house

buildings present but vacant. The 1951 Sanborn shows the lot being owned by BUG and is vacant with the exception of two small buildings near the southern edge of the Site.

Historical Atlas Reports for the City of Brooklyn were also reviewed during the time period when the MGP operated. Businesses that were in operation close to or adjacent to the Site during the operation of the MGP included the Chapman Docks/Marvel Oil Company (1929) located at the current 300 Maspeth Avenue parcel and the former Department of Sewers (1921-1968), Standard Rope & Twine Company (1899-1916), and the Banner Silk Dying Company (1929) all located at the current 184 Maspeth Avenue address (Appendix A). Chapman Docks/Marvel Oil Company, Standard Rope & Twine Company, and the Banner Silk Dying Company all likely used petroleum and the Standard Rope & Twine Company and the Banner Silk Dying Company likely used solvents and dyes in addition to petroleum. Additional information regarding the historical property usage at the 300 Maspeth Avenue property is provided in Section 2.8 below.

2.7 Post MGP Site History

According to internal notes written on a BUG facility plan, BUG maintained ownership of the property until September of 1951. Subsequently, the Site was used by unknown parties for storage (pipe and valves) for the period of 1965 to 1981, and appears to be vacant during the period of 1986 to 1988. The Site has been used as a solid waste transfer facility from 1989 to the present under the ownership of various parties (EDR, 2008a and 2008b,).

Historical Atlas Reports for the City of Brooklyn were also reviewed for the time period following MGP operation (Appendix A). Businesses that were in operation on the Site or in close proximity or adjacent to the Site following cessation of MGP operations included the former Fontana Transfer Station (2005) located on-Site at 254 Maspeth Avenue, The Newtown Creek Development Corporation/Salwen Paper Company, Inc. (1965-2003) located at 1 Rewe Street, Rockower-Sigawel Associates (2005) located at 1 Rewe Street, The Newtown Creek Development Corporation/Lack Carpet Company (1965-1982) located at 7-9 Rewe Street, The Chapman Docks Company/Crandall Oil & Putty Manufacturing Company (1929-1951) located at 7-9 Rewe Street and 300 Maspeth Avenue, The Chapman Docks Company/Unknown Oil Storage (1951) located at 7-9 Rewe Street and 300 Maspeth Avenue, The Lignum Chemical Works (1933) located along Vandervoort Avenue west of the Site, The Brooklyn Truck Wash (2001 to present) located at 184 Maspeth Avenue, The Royal Yarn Dying Corporation (1951-1994) located along Vandervoort Avenue west of the Site, and The Vander Dyeing & Finishing Corporation (2005) located along Vandervoort Avenue west of the Site (Appendix A). These properties all had or have the potential to use or store petroleum, solvents, dyes, PCBs, and other unknown chemicals. Additional information regarding the historical property usage at the 300 Maspeth Avenue and 7-9 Rewe Street properties is provided in Section 2.8 below.

2.7.1 Dust Suppression Well, DEC Letter and Shut down

To support the recycling operation and control the generation and off-Site wind transport of dust, the current property owner Cooper Tank and Welding Corp. (Cooper Tank) requires a dust suppression system along the top of the perimeter walls, and hoses to rinse mud and debris off vehicles before leaving their 222 Maspeth Avenue facility. In May 2003, they contracted a licensed New York well driller to install a water production well at 222 Maspeth Avenue. The well is located on the northern side of the parcel next to the main office building. The location of the well (designated PW-1 in the figures and K3504 on the Completion Report) is shown on Figure 2-4. A copy of the Completion Report – Long Island Well form and location sketch submitted to the New York Department of Environmental Conservation as a Certificate of Registration is included in Appendix C. The pumping

capacity of the well was listed as less than 45 gallons per minute, and pursuant to Environmental Conservation Law Sections 15-1501 and 15-1503 a Long Island Well Permit was not required. Since the well was not installed for drinking water, a Type 33 Use of Well Water for Other than Drinking Purposes Permit was filed with the New York City Department of Health and Mental Hygiene (NYCDHMH) under Article 141 of the New York City Health Code. A copy of the 2009 permit renewal is included in Appendix C. Requirements of the permit included the analyses for bacteria and the inspection of the well by a NYCDHMH field representative.

On December 16, 2009, AECOM sampled this well for chemical analysis, and VOCs, SVOCs, and various metals were detected. On January 10, 2010, AECOM measured 4.8 ft of a denser than water non-aqueous phase liquid (DNAPL) in the well. The measurements and observations were provided to NYSDOH. The well log included in the Completion Report does not include observations of DNAPL during drilling, and VOC and SVOC analyses were not required by the Type 33 Permit. In a letter between the NYSDOH and Henry Willems of the NYSDEC dated January 20, 2010, Albert DeMarco, Public Health Specialist, recommended that the well not be used for any purpose. The May 20, 2010 letter between Gannett Fleming Engineers, P.C. (GFE) and the IPP Inspection and Permit Section of the Bureau of Wastewater Treatment confirmed that Cooper Tank discontinued the use of the water well in January 2010 (please note the three stage carbon treatment system outlined in this letter was not installed). These letters are included in Appendix C. As a result of this work, the submersible pump and piping was removed from PW-1 but the well was not formally abandoned. Cooper Tank currently uses city water for dust suppression and vehicle washing operations.

2.8 Historic Land Use at Adjacent Properties

2.8.1 FedEx (300 Maspeth Avenue)

The property is located adjacent to the northeastern Site boundary and is occupied by FedEx (Figure 2-1). The approximately 5.4 acre property extends north to south from Maspeth Avenue to Rewe Street. The first known operations on the property were present in 1907, and consisted of a foundry supply company and storage buildings on the southern side of the property. The northern side consisted of marsh and drainage canals, which were progressively filled until full property occupancy in 1965. Operations are detailed in the table below, and include coal yards, lumber yards, oil handling, oil and putty manufacturing, fuel oil storage and truck filling, and motor freight with truck servicing.

Approximate Timeframe	Location on the Property	Company Name	Operations
Pre-1900 – 1965	Northern Half	Not Applicable	Marsh, Drainage, Canals, Empty Lot
1907	Southwest	Stanley Dogget	Foundry Supplies
1907	Southeast	J. P. Duffy Co.	Storage
1929	Southwest	The Chapman Docks Co./ Marvel Oil Corp.	Unknown
1929-1951	Southwest	The Chapman Docks Co./ E.V. Crandall Oil & Putty Mfg Co.	Oil & Putty Manufacturing
1929-1951	Southeast	The Chapman Docks Co./ The Hobin Hunter Feitner Lumber Co.	Lumber Yard
1947 – 1956	Southwest	The Chapman Docks Co./ Unknown	Fuel Oil Tanks & Truck Filling
1951	Southeast	The Chapman Docks Co./ Unknown	Lumber Yard

Approximate Timeframe	Location on the Property	Company Name	Operations
1951	Southeast	The Chapman Docks Co./ A.G. Feldman	Coal Yard
1965-1990	Entire Property	Newtown Creek Development Corp./ Branch Motor Express Inc.	Truck Service, Motor Freight Station
1991-1994	Entire Property	Newtown Creek Development Corp./ Roadway Package System Co.	Truck Service, Motor Freight Station
2001-2015	Entire Property	Newtown Creek Development Corp./ FedEx	Truck Service, Motor Freight Station

Six 10,000 gallon underground storage tanks (USTs) for gasoline are identified aligned north to south in between the former Marvel Oil Corporation office building and the E.V. Crandall Oil and Putty building on the 1951 Sanborn. It is presumed that these USTs were removed when the property was developed for the motor freight business in 1965. From approximately 1947 to 1956, a small portion of fuel oil storage complex, consisting of six 99,560 gallon above ground fuel oil tanks surrounded by a 10-foot high concrete wall, was present along the western boundary of the property and extended onto what is now 7-9 Rewe Street (Figure 2-5). Although the owner/operator of the complex is not identified, the location of the tanks is adjacent to and appears to be connected to structures identified as the Marvel Oil Corp on the 1929 Atlas (Appendix A). E.V. Crandall is another possible operator of the complex based on the proximity, configuration, and lack of any other identified operators on the 1951 Sanborn and 1954 aerial photograph.

2.8.2 Greenpoint Energy Center

National Grid's Greenpoint Energy Center Site is located north of and adjacent to the Site. The center is currently a liquefied natural gas (LNG) facility. Various portions of the facility have been used for industrial purposes throughout a history dating to at least 1838 and included the following operations outlined on the table below.

Approximate Timeframe	Operations
1838 – 1915	Peter Cooper Glue Factory
1870 - c 1907	Demuth Glass Manufacturing Company
1927 – 1952	MGP Water Gas Plant
1928 – 1952	Coke Oven Gas Plant
1952	Water Gas Plant converted to Oil Gas; Coke Ovens decommissioned
1968 – Present	LNG facility
1973 – 1989	SNG Plant

The facility is divided internally into two major operational areas: the LNG facility occupying the general northern half of the site, and gas transmission and operations support facilities in the southern half of the site. The entire property is fenced along its perimeter with the LNG facility fenced internally,

separating it from the operations area. The Greenpoint Energy Center operates 24-hours per day with full-time site-wide security.

2.8.3 7-9 Rewe Street and Fuel Oil Bulk Storage Facility

The 7-9 Rewe Street property is approximately 2.4 acres in size and is located to the south of 252 and 254 Maspeth Avenue and west of 300 Maspeth Avenue. The first known operations on the property were present in 1907, and consisted of an elevated coal car trestle electric trolley system running through the center of the parcel from northwest to southeast between the Equity MGP, the English Kills tributary of Newtown Creek, and the A. Busch & Sons – Bushwick Coal Yard. Prior to these operations, the area was a marsh with drainage running to the south to the English Kills tributary of Newtown Creek. Operations are detailed in the table below, and include the elevated trestle, storage for building materials, fuel oil storage and truck filling, carpet handling, material recycling, and industrial manufacturing and shipping.

Approximate Timeframe	Company Name	Operations
1907-1924	Unknown	Elevated Coal Car Trestle Electric Trolley System
1924 -1947	Chapman Dock Company	Building Materials storage, Out of Service Elevated Coal Car Trestle Electric Trolley System
1947 – 1956	The Chapman Docks Co./ Unknown	Fuel Oil Tanks & Truck Filling
1956-1982	Unknown	Unknown
1965-1982	Newtown Creek Development Corp./ Lack Carpet Co. Inc.	Carpet Handling
1986-1990	Newtown Creek Development Corp./ Boro Recycling	Material Recycling
1991-2007	Newtown Creek Development Corp./ Global Moving & Storage	Industrial/ Manufacturing (Shipping Warehouse) (UST)

As discussed in Section 2.8.1, a fuel oil storage complex, consisting of six 99,560 gallon above ground fuel oil tanks surrounded by a 10 foot high concrete wall was present on the 7-9 Rewe Street property from approximately 1947 to 1956. A small portion of the complex extended onto 300 Maspeth Avenue where it is adjacent to and appears to be connected to structures identified as the Marvel Oil Corp on the 1929 Atlas. E.V. Crandall is another possible operator of the complex based on the proximity, configuration, and lack of any other identified operators on the 1951 Sanborn and 1954 aerial photograph.

2.9 Potential Source Areas for Environmental Impacts

Structures associated with the Equity former MGP are shown on Figure 2-4, and included the No. 1 Relief Holder, tar tanks, drip tanks, separators, pump houses, tar wells, purifier house, generator and boiler rooms/houses, condensers, exhausters, coal storage and elevated coal car trolley, oil storage tanks, offices and sheds. Specific structures that present potential source areas for environmental impacts at the Site include:

Structure	Location
Holder No. 1 430,000 cu ft Relief Holder/Gas Holder	222 Maspeth Ave
Relief Holder/Tar Tank/Settling Tank	222 Maspeth Ave
Fuel Oil/Tar Tank	222 Maspeth Ave
Drip Tanks	222 Maspeth Ave
Separator	252 Maspeth Ave
Separator	254 Maspeth Ave
Oil House/Oil Storage Tanks No. 1 and No. 2	254 Maspeth Ave
No. 3 Oil Storage Tank	254 Maspeth Ave

The No. 1 Relief Holder was observed in borings SB-8 and SB-13, and the Oil Storage Tank No. 2 was observed in Test Pit TP-2.

2.10 Previous and Concurrent Investigations

2.10.1 Geotechnical Investigations by Cooper Tank

Previous investigation activities were conducted on portions of the Site in 2004 and 2005 by the current Site owner, as listed below:

- For the 252 Maspeth Avenue property, a Phase II Environmental Subsurface Investigation (ESI) was conducted in March 2005 by GFE on behalf of Cooper Tank, who was the potential lessee of the property (GFE, 2005a). GFE installed four soil borings on the property and collected soil samples which were analyzed for volatile organic compounds (VOCs), semivolatile organic compounds (SVOCs), polychlorinated biphenyls (PCBs), and 13 Priority Pollutant Metals plus barium. Temporary PVC wells were installed in two of the borings (B-1 and B-4), and groundwater samples were collected and analyzed for the same constituents as the soil samples. In soils, VOCs, SVOCs, and various metals were detected in samples from all four borings. PCBs were detected in only one soil sample. Odors and staining were observed in all four borings. In groundwater, VOCs, SVOCs and various metals were detected in samples collected from both temporary wells. PCBs were detected in one groundwater grab sample, but the detection is likely turbidity related given the relative insolubility of PCBs in water.
- For the 254 Maspeth Avenue property:
  - A Phase II ESI was conducted in September 2004 by Energy & Environmental Analysts, Inc. (EEA) on behalf of Spencer Realty Corporation (the property owner) and Cooper Tank (the potential property buyer) (EEA, 2004). EEA installed 6 soil borings on the property and collected soil samples which were analyzed for VOCs, SVOCs, and RCRA metals. SVOCs and various metals were detected in all six borings. VOCs were detected in two of the borings. The subsurface geology was characterized to the completion depth of the borings.
  - A Phase I Environmental Site Assessment (ESA) was conducted in October 2004 by GFE on behalf of Cooper Tank, who was the potential buyer of the property (GFE, 2004).

GFE conducted a records search, interviews and Site visit. Surficial soil staining was observed on-Site. A Phase II investigation of potential soil and groundwater impacts was recommended.

- For the 252 and 254 Maspeth Ave properties, GFE performed geotechnical investigation work on behalf of Cooper Tank in September 2006 (GFE, 2006b). GFE installed five soil borings to investigate the geology below these properties. A report is not available, but a map and boring logs are provided in Appendix B.

These historic investigation locations are shown on Figure 2-6. A copy of each report is provided in Appendix B.

2.10.2 FedEx (300 Maspeth Ave.) Release Numbers and Investigations

Based on information collected from a Freedom of Information Law (FOIL) request on NYSDEC Spill #'s 0202804 and 0204002 at 300 Maspeth Avenue, Spill #0202804 was issued in 2002 after GFE, while working for FedEx, reported observing petroleum impacted soils during the removal of 20 USTs (550 gallon capacity each) and 900 tons of impacted soils (GFE, 2002). The work was performed from June 17 to July 3, 2002 along the northeast property boundary of 300 Maspeth Avenue. Additional soil was removed in November 2002 after GFE advanced 12 soil borings in a 25 foot grid to delineate impacts to the north of the original UST excavation (see Figure 2-7). GFE completed this work under contract with FedEx. On January 8, 2003, GFE uncovered a 500-gallon UST located in the northeast corner of the property, removed residual oil sludge in the tank, and removed the tank for disposal.

Spill #0204002 was issued on July 17, 2002 when "black stained soils exhibiting a strong petroleum odor" were observed by GFE during the removal of concrete for underpinning for a new foundation for FedEx. On August 2, 2002, GFE excavated six test pits to approximately 9 ft bgs (1 ft into the water table) to delineate the extent of the impacted soils (GFE, 2002). Copies of documents related to these two spills are included in Appendix B.

In emails and letters from 2002 to 2005, GFE suggests that the impacted soils were located on the southwest portion of the RI Study Area where a former fuel oil terminal was located in 1951 and 1954. AECOM reviewed the 1907, 1933, 1951, and 1965 Sanborn and the 1954 and 1966 aerial photos (Attachment B). These documents show the location of a fuel oil terminal in 1951 and 1954. While it is unclear from the Sanborn maps who owned and operated the oil terminal (See Section 2.8), the facility was clearly not related to the operation of the MGP. The oil terminal was located approximately 160 ft south of the MGP property, and its construction post-dates the closure of the MGP operations in 1932.

On December 8 and 9, 2003, GFE installed six soil borings and wells, shown on Figure 2-7. Soil samples were collected to the water table with the interval with highest PID submitted for analyses. Wells were installed to 20 ft bgs with a 15-foot screen. Groundwater samples were collected on Jan 9, 2004, as well as Dec. 29, 2004, Feb. 24, 2005, June 6, 2005, and Sept 28, 2005. No non-aqueous phase liquid was observed in any wells.

On December 22, 2005, NYSDEC deactivated Spill #'s 020804 and 0204002 based on GFE's October 2005 Final Groundwater Report that states that the "groundwater contaminant plume is stagnant and representative of regional groundwater quality" (GFE, 2005b). On Feb 15, 2006, GFE abandoned the wells (GFE, 2006a).

Observations of soil samples collected during these investigations contained typical urban fill materials (gravel, sand, crushed concrete, brick, etc.). No impacts were noted, with the exception of black stained soils with petroleum odor. No soil descriptions were collected below the water table, encountered at about 10 ft bgs at the property. Groundwater flows to the east in the central portion of the property, and then flows north in the eastern part of the property. Constituent exceedances in groundwater follow no clear pattern, and included the BTEX compounds and some PAHs, although no exceedances were detected at MW-6 along the northern property boundary.

2.10.3 Greenpoint Energy Center Remedial Investigation

National Grid is currently conducting a Remedial Investigation (RI) of the Greenpoint Energy Center. To date, the RI has focused on areas along the bulkhead and the Maspeth Avenue corridor. Future RI work will be completed in the interior of this site. All work is being conducted under NYSDEC oversight.

2.10.4 Newtown Creek

The Newtown Creek Superfund Site is located east of the Site. English Kills, a tributary to Newtown Creek, is the closest surface water to the Site and is located approximately 700 ft south and east of the Site. Newtown Creek and its tributaries are currently being investigated by the USEPA.

3.0 Investigation Activities

This section provides a description of the activities performed during the RI and PDIs and the methods used for conducting the fieldwork at the RI Study Area. Unless otherwise noted in the following sections, the procedures used were consistent with the methods and procedures described in the NYSDEC-approved RIWP and addenda, FSAP, QAPP, HASP, and CAMP. Each field activity performed during the investigation, grouped by field task or environmental media, is described in the following sections. The RI sample locations, and the locations of the samples collected during the PDIs are shown on Figure 3-1.

3.1 Chronology of Investigations

Multiple phases of investigation activities were completed in the RI Study Area as part of the RI and as PDIs for two interim remedial measures (IRMs) conducted at the Site. This section presents a chronology of these investigation phases and IRMs and summarizes the activities conducted during each phase of work.

3.1.1 Remedial Investigation Phases

The RI activities were conducted between 2009 and 2015 in several phases. This section describes the scope of work conducted for each phase.

3.1.1.1 Remedial Investigation (2009 – 2010)

The objectives of the Remedial Investigation Work Plan (RIWP) (AECOM, 2009) were to:

- Collect additional data to more completely determine the surface and subsurface characteristics of the RI Study Area.
- Determine the nature and extent of environmental impacts in soils, soil vapor, and groundwater.
- Identify potential routes of off-Site migration of environmental impacts within the RI Study Area from Site sources.
- Perform an exposure assessment to evaluate the pathways by which human receptors (either on-Site or off-Site) may be exposed to environmental impacts.
- Further develop the dataset necessary to allow preparation of a Feasibility Study to evaluate remedies that will eliminate the potential threat to public health or the environment posed by the Site.

From September 2009 through March 2010, the following field activities were completed for the RI:

- Completed underground utility clearance activities, including geophysical utility survey and soft digging locations for ground-disturbing activities.
- Advanced 32 soil borings: 5 by direct push, 26 by hollow stem auger, and one by “drive and wash” methods using casing and a roller bit.

- Converted 17 borings to permanent monitoring wells:
  - Seven shallow (A) wells installed to total depths ranging from 14.5 to 17 ft bgs,
  - Seven intermediate (B) wells installed to total depths ranging from 37.5 to 46 ft bgs, and
  - Three deep (C) wells installed to total depths ranging from 79 to 81 ft bgs.
- Converted one boring to a temporary well screened from 5 to 15 ft bgs, and removed temporary well immediately after collecting a groundwater sample.
- Developed monitoring wells not sooner than 24 hours after their installation.
- Excavated two test pits at 254 Maspeth Avenue to a depth of 8 to 8.5 ft bgs, and one test pit at 252 Maspeth Avenue to a depth of 13.9 ft bgs; test pits were backfilled with native material.
- Collected four surface soil samples (0-2 inches bgs), 69 subsurface (greater than 2 inches bgs) soil samples, and 18 groundwater samples (including a sample from Cooper Tank's on-Site non-potable use well, PW-1). Collected associated quality assurance/quality control (QA/QC) samples. The samples collected are listed in Table 3-1. Submitted samples under proper chain-of-custody procedures to H2M Labs, Inc. for the analyses listed in Table 3-1.
- Collected two rounds of well gauging data for NAPL and groundwater elevations (one round while PW-1 was in operation, and one round when PW-1 had been out of service for over 72 hours).
- Performed hydraulic conductivity testing by the pneumatic slug test method at seven wells: two shallow wells, two intermediate wells, and three deep wells.
- Performed 40 hour tidal cycle monitoring at nine monitoring wells: three shallow wells, three intermediate wells, and three deep wells.
- Installed two permanent sub-slab soil vapor collection points, one at 222 Maspeth Avenue and one at 252 Maspeth Avenue, and collected two rounds of soil vapor (SV), indoor air (IA), and ambient air samples for the laboratory analyses listed on Table 3-2. Note that the RIWP called for only one round of IA/SV sampling (conducted in November 2009); however, based on the results, a second round was conducted (in March 2010) to confirm the findings. As discussed in Section 5.6 of this report, the initial two rounds of IA/SV data for the building at 222 Maspeth Ave showed elevated risk due to vapor intrusion. Subsequently, remedial work was conducted to seal off potential vapor migration pathways and two additional rounds of IA/SV sampling were conducted in August 2010 and February 2011 to confirm the effectiveness of the remedial work.
- Performed NAPL mobility testing at wells MW-3B and PW-1.
- Surveyed investigation locations (soil borings, monitoring wells, test pits, and soil vapor points) for horizontal coordinates, ground surface elevation, and top of casing elevations (monitoring wells and on-Site pumping well PW-1).

3.1.1.2 Remedial Investigation – Addendum No. 1 (2011 – 2012)

The objectives of RIWP Addendum No. 1 (National Grid, 2011b) were to:

- Evaluate the presence and condition of the former tar tank and tar separator along the northern Site boundary, and determine the quality of surrounding soils.

- Further delineate NAPL observed at depth at RI location SB-1 along Vandervoort Avenue to obtain a non MGP-impacted background sample/well.
- Further delineate NAPL observed at depth at RI locations near Maspeth Avenue.
- Further delineate NAPL observed at depth at RI locations east of the property in the direction of deep groundwater flow.
- Further delineate NAPL observed at depth at RI locations near the southern property boundary.
- Further delineate the presence or absence of the intermediate clay unit that appeared to pinch out in the vicinity of the former gas holder at the 222 Maspeth Avenue parcel.
- Complete all proposed borings to the top of the Gardiner's Clay unit (which was assumed to be encountered in RI soil boring SB-1 at a depth of 97 ft bgs) to ensure that no NAPL is migrating on this surface.

From September through November 2011, the following field activities were completed as part of the RIWP Addendum No. 1:

- Completed underground utility clearance activities, including geophysical utility survey and soft digging locations for ground-disturbing activities.
- Advanced nine soil borings by sonic drilling. Note that the RIWP Addendum No. 1 (National Grid, 2011b) called for advancement of 15 soil borings; however, six borings (SB-25, SB-26, SB-27, SB-28, SB-31 and SB-32) could not be completed during this mobilization due to access issues. These borings were advanced during the RI Addendum No. 2 work as discussed below. In addition, SB-20 was not advanced to the Jameco Gravel at this time, but a separate boring (SB-20J) was completed during the RI Addendum No. 2 work.
- Converted seven borings to permanent monitoring wells. Note that RIWP Addendum No. 1 called for 12 monitoring wells to be installed; however, seven of the planned wells (MW-8J, MW-11B/C, MW-12B/C, and MW-13B/C) were not installed during this mobilization. Wells MW-8J and MW-13B/C were never installed and the others were installed during the RIWP Addendum No. 2 mobilization as discussed below. The wells installed during the RIWP Addendum No. 1 work included:
  - One shallow (A) well installed between 5 and 15 ft bgs,
  - Three intermediate (B) wells installed to total depths ranging from 42 to 49 ft bgs; note that two of these wells (MW-14B and MW-15B) were not planned for in RIWP Addendum No. 1, and
  - Three deep (C) wells installed to total a depth of 82 ft bgs.
- Developed monitoring wells not sooner than 24 hours after their installation.
- Excavated one test pit at 254 Maspeth Avenue to a depth of 8 to 8.5 ft bgs; test pit was backfilled with native material. Note that test pit work was completed concurrent with the PDI for Shallow Soil Removal activities discussed in Section 3.1.2.1 below.
- Collected 24 subsurface (greater than 2 inches bgs) soil samples and no groundwater samples. Collected associated QA/QC samples. The samples collected are listed in Table 3-1. Note that wells MW-8A/B/C were sampled in August 2012 and wells MW-9C and MW-10C were sampled in February 2013 as part of the RIWP Addendum No. 2 activities, although the

sampling had been planned as part of the RIWP Addendum No. 1 scope of work. Submitted samples under proper chain-of-custody procedures to TestAmerica Laboratories, Inc. (TestAmerica) and Spectrum Analytical, Inc. (Spectrum) for the analyses listed in Table 3-1.

- Surveyed investigation locations for horizontal coordinates, ground surface elevation, and top of casing elevations, as appropriate.

3.1.1.3 Remedial Investigation – Addendum No. 2 (2012 - 2013)

The objectives of RIWP Addendum No. 2 (National Grid, 2012a) were to:

- Further delineate environmental impacts at areas adjacent to the Site down to the contact with the Gardiner's Clay, and
- Advance one soil boring (SB-20/MW-8J) to identify the elevation of the Jameco Gravel and assess potential impacts and determine the soil and groundwater quality below the surface of the Gardner's Clay.

In July through August 2012 and January through February 2013, the following field activities were completed as part of the RIWP Addendum No. 2:

- Completed underground utility clearance activities, including geophysical utility survey and soft digging locations for ground-disturbing activities.
- Advanced 10 soil borings by sonic drilling. Note that six of these borings (SB-25, SB-26, SB-27, SB-28, SB-31 and SB-32) were included in the RIWP Addendum No. 1, but were not installed in 2011 due to access limitations. In addition, boring SB-20J was advanced through the Jameco Gravel and into bedrock.
- Converted two borings into two pairs of permanent nested monitoring wells. Note that these wells (MW-11B/C and MW-12B/C) were originally planned in the RIWP Addendum No. 1. The wells installed during the RIWP Addendum No. 2 work included:
  - Two intermediate (B) wells installed to total depths ranging from 40.5 to 42 ft bgs, and
  - Two deep (C) wells installed to total depths ranging from 88.5 to 102.5ft bgs.
- Installed one temporary well at SB-20J between 70 and 80 ft bgs.
- Developed monitoring wells not sooner than 24 hours after their installation.
- Collected 17 subsurface (greater than 2 inches bgs) soil samples and 10 groundwater samples. Collected associated QA/QC samples. The samples collected are listed in Table 3-1. Note that these groundwater samples were originally planned under RIWP Addendum No. 1, but were collected as part of the RIWP Addendum No. 2 activities. Submitted samples under proper chain-of-custody procedures to TestAmerica for the analyses listed in Table 3-1.
- Surveyed investigation locations for horizontal coordinates, ground surface elevation, and top of casing elevations, as appropriate.

3.1.1.4 Remedial Investigation – Addendum No. 2 Modification (2013)

Based on conversation with NYSDEC regarding the preliminary results from the RI Addendum No. 2 activities, a RIWP Addendum No. 2 Modification (National Grid, 2013a) was submitted to further delineate the downgradient extent of dissolved phase constituents east of the Site.

In July and August 2013, the following field activities were completed as part of the RIWP Addendum No. 2 Modification:

- Completed underground utility clearance activities, including geophysical utility survey and soft digging locations for ground-disturbing activities.
- Advanced four soil borings by sonic drilling methods.
- Converted all four borings into four monitoring well triplets (12 wells total). The wells installed during the RIWP Addendum No. 2 Modification work included:
  - Four shallow (A) wells installed to total depths ranging from 20 to 25 ft bgs,
  - Four intermediate (B) wells installed to total depths ranging from 40 to 50ft bgs, and
  - Four deep (C) wells installed to total depths ranging from 90 to 112.7 ft bgs.
- Developed monitoring wells not sooner than 24 hours after their installation.
- Collected 12 groundwater samples and associated QA/QC samples. The samples collected are listed in Table 3-1. Submitted samples under proper chain-of-custody procedures to Accutest Laboratories (Accutest) for the analyses listed in Table 3-1.
- Surveyed investigation locations for horizontal coordinates, ground surface elevation, and top of casing elevations, as appropriate.

3.1.1.5 Remedial Investigation – Addendum No. 3 (2014)

The purpose of RIWP Addendum No. 3 (National Grid, 2013b) work was to investigate former tidal channels at the current FedEx facility at 300 Maspeth Avenue and at the current 7-9 Rewe Street property. These tidal channels were filled as the area was developed from the late 1800s through the mid-1900s. The purpose of this work was to determine the presence or absence of environmental impacts in these former channel areas.

In May and October 2014, the following field activities were completed as part of the RIWP Addendum No. 3:

- Surveyed and marked the locations of the former tidal channels based on historic documents.
- Completed geophysical surveys using ground penetrating radar of the tidal channels to determine if former channel morphology is present in the subsurface and to identify best areas for subsurface investigation.
- Completed underground utility clearance activities, including geophysical utility survey and soft digging locations for ground-disturbing activities.
- Advanced 38 soil borings by direct push methods to approximately 30 ft bgs (bottom of the meadow mat).
- Collected 13 subsurface (greater than 2 inches bgs) soil samples and associated QA/QC samples. The samples collected are listed in Table 3-1. Submitted samples under proper chain-of-custody procedures to Accutest for the analyses listed in Table 3-1.
- Surveyed investigation locations for horizontal coordinates, ground surface elevation, and top of casing elevations, as appropriate.

3.1.1.6 Remedial Investigation – Addendum No. 4 (2015)

The purpose of RIWP Addendum No. 4 (National Grid, 2015) was to investigate subsurface conditions to the south of the Site beneath current buildings at 1 and 7-9 Rewe Street in order to determine the presence or absence of potential impacts in soils beneath the Rewe Street buildings focused on areas where former tidal channels were present. This investigation also evaluated soil vapor and indoor air samples from the building areas adjacent to (south and west of) the former MGP.

In March through May 2015, the following field activities were completed as part of the RIWP Addendum No. 4:

- Completed underground utility clearance activities, including geophysical utility survey and soft digging locations for ground-disturbing activities.
- Advanced eight soil borings by direct push methods to the top of the “intermediate clay” unit if detected, or a maximum depth of approximately 50 ft bgs.
- Collected 25 subsurface (greater than 2 inches bgs) soil samples and associated QA/QC samples. The samples collected are listed in Table 3-1. Submitted samples under proper chain-of-custody procedures to TestAmerica for the analyses listed in Table 3-1.
- Installed three temporary sub-slab soil vapor collection points, two at 1 Rewe Street at the north and south ends of the building and one at 7-9 Rewe Street. Collected one round of SV/IA samples, and an ambient air sample for the laboratory analyses listed on Table 3-2.
- Surveyed investigation locations for horizontal coordinates, ground surface elevation, and top of casing elevations, as appropriate.

3.1.2 Pre-Design Investigations

Two phases of PDI were conducted at the Site in order to support development of IRMs for the Site.

3.1.2.1 PDI for Interim Remedial Measure - Shallow Soil Excavation (2011)

The owner of 254 Maspeth Avenue, Cooper Tank, was in the process of obtaining a NYSDEC Part 360 Permit for operating a recycling facility. This permit required construction of a minimum 8-inch thick concrete pad across the entire surface of the Site, a storm water collection system, and a 30-foot high wall along the perimeter of the Site. These activities were expected to be invasive and potentially encounter r environmental impacts observed during the ongoing RI. As a result, National Grid and the NYSDEC agreed that an IRM would be conducted on the 254 Maspeth Avenue property consisting of removal of NAPL saturated soils above the water table. A PDI was conducted to gather additional information needed to ensure a safe and effective design of the IRM, facilitate its implementation, and provide soil pre-characterization for disposal.

The objectives of the PDI for Shallow Soil Excavation were to:

- Delineate the horizontal extent of the visually contaminated soils located around SB-4, TP-2, and SB-12.
- Confirm the vertical extent of the visually contaminated soils to be removed.
- Investigate the unsaturated soils located within the footprint of the proposed perimeter wall.
- Pre-characterize soil for disposal options.

The initial PDI Work Plan (National Grid, 2011a) was modified in September 2011 (National Grid, 2011c) to include four test pits on the 252 Maspeth Avenue parcel with collection of soil samples for waste characterization. The PDI test pit locations are shown on Figure 3-2.

In September 2011, the following field activities were completed as part of the PDI for Shallow Soil:

- Completed underground utility clearance activities, including geophysical utility survey and soft digging locations for ground-disturbing activities.
- Excavated 21 test pits (17 at 254 Maspeth Avenue and four at 252 Maspeth Ave) to the water table (with the exception of TP-12, which was terminated above the groundwater surface due to nuisance odor conditions generated during excavation of this test pit). The perimeter test pits were advanced to the water table at a spacing of approximately 50 ft and extended a minimum of 15 ft into the 254 Maspeth Avenue property, from the property perimeter. Two additional step-out locations (TP-12A and TP-15A) were excavated at 25 foot intervals along the perimeter due to the presence of visual impacts in TP-12 and TP-16. Two test pits (TP-2B and TP-2C) were excavated to evaluate the presence and extent of tar observed at RI location SB-4 and test pit TP-2. Excavation was accomplished using a backhoe under the supervision of an AECOM geologist. Each test-pit was backfilled with native material.
- Collected 10 subsurface (greater than 2 inches bgs) soil samples and associated QA/QC samples. The samples collected are listed in Table 3-1. Submitted samples under proper chain-of-custody procedures to Spectrum for the analyses listed in Table 3-1.
- Surveyed investigation locations for horizontal coordinates, ground surface elevation, and top of casing elevations, as appropriate.

3.1.2.2 PDI for Interim Remedial Measure - Potential Barrier Wall Design / NAPL Recovery System (2012)

In 2012, National Grid and NYSDEC discussed the possibility of implementing an IRM to recover NAPL and to limit the potential for off-Site migration of NAPL beyond the site boundary to other adjacent land-side properties. NAPL was observed above a clay layer beneath the Site at a depth of approximately 50 ft bgs. The limits of NAPL were determined during the RI and considered stable based on the progressive change in NAPL distribution from saturated zones noted predominantly on-site to areas containing NAPL coatings, staining, and sheen at distal areas both on-site and off-site. The material is in a non-saturated state and no longer has sufficient volume to create the pressure head for further migration (Gusawa and Kueper, 2003).

Both a barrier wall system and a NAPL recovery system comprised of closely spaced recovery wells were considered, and a PDI was planned to gather data to facilitate the decision. Ultimately, National Grid, with approval of NYSDEC, installed a NAPL recovery system using closely spaced recovery wells (as discussed in Section 6.4) as an IRM.

The findings regarding the extent of impacts are discussed in Section 5.2 and 9.1.

The first part of the PDI (National Grid, 2012b) was conducted to gather geotechnical information needed to ensure a safe and effective design for potential installation of subsurface barrier walls along a portion of the 252 and 254 Maspeth Avenue. The PDI investigation locations are shown on Figure 3-2. The second part of the PDI (National Grid, 2012c) was implemented to install test wells in areas

where NAPL had been observed to evaluate the NAPL recovery potential and inform the spacing and final location of perimeter recovery wells.

In August and September 2012, the following field activities were completed as part of this PDI:

- Completed underground utility clearance activities, including geophysical utility survey and soft digging locations for ground-disturbing activities.
- Advanced seven geotechnical soil borings by hollow-stem auger methods to a maximum depth of 60 ft bgs or the top of the intermediate clay if encountered first. Continuous standard penetration tests (ASTM D1586) were conducted in each boring, and soil from each was logged by a geologist or engineer using the visual-manual procedure (ASTM D2488).
- Collected 14 soil samples and analyzed them for classification of soils for engineering purposes (ASTM D2487), including grain size analysis and Atterberg limits.
- Converted the seven borings into 4-inch PVC wells with 20-slot screens using a 6.25-inch ID hollow stem augers with an expendable plug advanced down the borehole to a depth that allowed the well to screen the top of the intermediate clay surface with an appropriate length sump. Four-inch diameter Schedule 40 PVC well materials were used, including 2-foot minimum length sump and a 10-foot screen.
- Following installation, the wells were developed to remove solids and promote hydraulic connection with the aquifer.
- The wells were then periodically monitored to determine if NAPL was collecting in any of the wells. If present, NAPL was periodically removed to evaluate relative recharge / recoverability characteristics.

3.1.3 NAPL Recovery Well Installations (2013)

Based on the results from the PDI for Potential Barrier Wall Design / NAPL Recovery System, an IRM was developed to implement a system of NAPL recovery wells within and along the perimeter of the Site. A detailed discussion of this IRM is provided in Section 6.4.

As part of the IRM, 23 recovery wells were installed between March 3 to April 10, 2013, five on-Site and 18 along the perimeter of 222, 252 and 254 Maspeth Ave properties. The recovery well locations are shown on Figure 3-2. The perimeter locations were spaced at approximately 18 ft on center, with the exception of the area along the driveway of 254 Maspeth where the presence of a subsurface structure required spacing of approximately 30 ft between the three NAPL recovery wells (RW-6, RW-7 and RW-8). Soil borings were advanced at each of the locations, and soil samples collected for observation. Copies of the boring logs provided in Appendix D. Based on the observations, the bottom of the well screen was set at the bottom of the observed NAPL saturated interval.

3.2 Investigation Methods

This section provides a description of the methods used for conducting the fieldwork at the RI Study Area. Unless otherwise noted in the following sections, the procedures used were consistent with the methods and procedures described in the NYSDEC-approved RIWP, FSAP, QAPP, HASP, and CAMP. Each field activity performed during the investigation, grouped by field task or environmental media, is described in the following sections. The RI and PDI sample locations are shown on Figures 3-1 and 3-2.

3.2.1 Subsurface Utility Location

Prior to the start of any intrusive fieldwork, clearance of underground utilities was performed. The utility locating was initiated by contacting Dig Safely New York. Each company or municipality that had subsurface utilities present in the investigation area marked out their utility lines prior to the initiation of the subsurface work. Copies of available city sewer and water maps from the RI Study Area were obtained and reviewed during underground utility clearance procedures. Following the utility mark out, each sampling location was then scanned using ground penetrating radar (GPR) and electromagnetic (EM) survey methods to confirm the location of marked utilities and/or to identify other unmarked utilities. Lastly, all boring/well locations were pre-cleared by hand digging or vacuum excavating to a depth of 5 ft to check for potential utilities not located by Dig Safely or geophysical methods.

3.2.2 Surface Soil Sampling

Exposed surface soils are generally limited to the eastern areas of the Site within the 252 and 254 Maspeth Avenue parcels. Five surface soil samples were planned; however, four samples (plus one field duplicate sample) were collected during the initial 2009 RI activities, at the locations shown on Figure 3-1. Proposed sample SS-1 was not collected because the boring was installed through a concrete sidewalk and no surface soil was available for collection near the boring.

The surface soil samples were collected from the 0 to 2-inch bgs interval. The samples were collected using a properly decontaminated stainless steel or disposable polyethylene trowel.

The surface soil samples were analyzed for the following parameters (USEPA, 1980 – SW846):

- Full Target Compound List (TCL) VOCs by USEPA Method 8260B
- Full TCL SVOCs by USEPA Method 8270C
- Target Analyte List (TAL) Metals by USEPA Method 6000-7000 Series
- TCL Pesticides by USEPA Method 8081A
- TCL Herbicides by USEPA Method 8151A
- Polychlorinated Biphenyls (PCBs) (as Aroclors) by USEPA Method 8082
- Free cyanide (extraction by USEPA Method 9013A and analysis by Microdiffusion, ASTM International Method D4282-02)

Following sample collection, any remaining soil was used to backfill the sample area. Decontamination of sampling equipment was performed between sample locations in accordance with field procedures in the RIWP. RI Study Area sample locations were surveyed, as described in Section 3.2.14.

Sample details including sample ID, date, and laboratory analysis are summarized on Table 3-1. Analytical results are discussed in Section 5.

3.2.3 Test Pit Excavations

Three test pits were advanced during the initial RI work in 2009, one test pit was advanced during the RIWP Addendum No. 1 activities in 2011, concurrent with the completion of 21 test pits as part of the PDI for Shallow Soil Removal.

The RI test pits were focused in and around the former drip tanks/tar separator in the center of the Site, the gas/oil storage house and former No. 3 oil tank along the eastern edge of the property, the former separator and tar tank underlying the boiler house along the northern Site boundary, and the former tar tank and tar well. The RI test pit locations are shown on Figure 3-1. The PDI test pits were focused around the perimeter of the 254 Maspeth Ave property and areas where soil was going to be disturbed by redevelopment activities, as discussed in Section 3.1.2 and shown on Figure 3-2.

The test pits were excavated with a backhoe or excavator using methods presented in the FSAP, with samples collected from the bucket of the excavator. The test pits were logged by a geologist recording such data as the presence of fill material or subsurface structures, the nature of each geologic unit encountered, observations regarding moisture content, the results of PID readings, and visual and olfactory observations regarding the presence of hydrocarbon-like residuals.

Sample details including sample ID, sample date, and laboratory analysis are summarized on Table 3-1. Test pit logs are included in Appendix E. The results of the observations made and the results of subsurface soil analytical testing performed during the test pit excavations are discussed in Sections 4 and 5, respectively.

3.2.4 Soil Borings and Subsurface Soil Sampling

As discussed in Section 3.1, from 2009 through 2015, 102 soil borings were advanced in the RI Study Area as part of the RI work under the RIWP and Addenda. As outlined in Section 3.1.3, all boring locations were hand cleared to a minimum depth of 5 ft bgs for utility clearance purposes.

The borings completed in the overburden soil were advanced to varying depths as specified in the RIWP and Addenda. Table 3-3 lists all the soil borings completed as part of the RI activities and their final completion depths. Figure 3-1 shows the locations of the RI soil borings. Boring logs are provided in Appendix D.

A variety of drilling methods were used including hollow stem auger, direct push, drive and wash, and sonic drilling. The drillers contracted for different phases of the work included: Fenley & Nicol Environmental, Inc. of Deer Park, New York; Paragon Environmental Construction, Inc. of Brewerton, New York; Boart Longyear, Inc. of Northborough, Massachusetts; Zebra Environmental Corp. of Lynbrook, New York; and Glacier Drilling LLC of Durham, Connecticut.

Each of the drilling methods allowed for continuous soil samples to be taken from the ground surface to the bottom of the borehole for both field characterization and for the collection of samples for chemical analyses. For field characterization, soil samples were screened using a PID and were logged for geology and observations of impacts by a geologist.

The RIWP and Addenda specified the number of soil samples to be collected for chemical analysis and intervals they were to be collected from. Typically, soil samples were collected at intervals with the highest observed impact (based on olfactory and visual observation and PID readings) and at lower intervals without observable impacts (if impacts are encountered) or the bottom of the boring to confirm “non-impacted” conditions.

A total of 141 soil samples (not including field duplicate samples) were collected from soil borings for chemical analysis during the RI. Table 3-1 lists the laboratory analyses performed for each soil sample. Most of the soil samples were analyzed for VOCs, SVOCs, metals and free cyanide (by Microdiffusion method). A subset of soil samples were analyzed for available or total cyanide instead

of free cyanide. A subset of the samples was analyzed for PCB aroclors. Another subset of the samples were analyzed for TPH, DRO and/or GRO. A small subset of soil samples from borings were analyzed for pesticides and herbicides.

Sampling tools were decontaminated between sample intervals and between borehole locations in accordance with field procedures in the RIWP (AECOM, 2009).

Table 3-3 lists the boring locations that were completed as monitoring wells. The remaining borings were backfilled with grout, tremied to the surface. Soil cuttings were placed in 55-gallon drums, labeled, and later disposed at an approved off-site facility (see Section 3.2.15 for Investigation Derived Waste (IDW) details). Following boring activities each location was surveyed as described in Section 3.2.14.

The results of observations made during soil boring advancement are discussed in Section 4. Analytical results are discussed in Section 5.

3.2.5 Monitoring Well Installation

A total of 40 monitoring wells were installed during the RI and RI Addendum phases to obtain groundwater data at locations upgradient, crossgradient, and downgradient of various former MGP features. Most of the monitoring wells were constructed as 2-inch diameter wells using schedule 40 polyvinyl chloride (PVC). Three of the monitoring wells were constructed as 1-inch diameter PVC wells and two wells were constructed using 1-inch prepacked wells. About half of the monitoring wells had 10-slot well screens and the rest had 20-slot well screens. Most of the wells were constructed with a 2-foot sump interval.

Monitoring wells were set in three generalized zones within the water-saturated overburden: shallow (A-series) wells screened at the water table, intermediate (B-series), and deep (C-series). Collocating/pairing wells into a single borehole was approved by the NYSDEC and is described in the following paragraph.

At several locations, monitoring wells screened in the deep and intermediate zones were co-located within one borehole and the shallow well was completed adjacent to the paired location as a single well. For the co-located wells, the deep well was installed first with the bottom of the borehole backfilled with bentonite to within 6-inches of the top of the sump. A 2-foot sump was installed at the bottom, and then a 10-foot screen with a sand pack to just above the lowest screened interval. Before installing the intermediate zone well, bentonite was added (as needed) to the borehole above the deep screened interval to within 6-inches of the bottom of the intermediate screen. A 2-foot sump was installed, then a 10 foot screen, with a sand pack and a riser to just below grade. Above the intermediate zone sand pack, a 2-foot bentonite seal was placed, followed by tremie grout to just below the ground surface. The paired wells were completed at the surface with one flush-mounted, limited access, road box. The entire construction of the intermediate zone has the riser of the deep zone well adjacent to it. For locations with an additional shallow zone well, a second boring adjacent to the deep and intermediate well cluster was advanced for installation of the shallow zone well. Locations with this nested well construction include SB-20/MW-8A/B/C, SB-25/MW-11B/C, SB-26/MW-12B/C, SB-36/MW-16B/C, SB-37/MW-17B/C, SB-38/MW-18B/C and SB-39/MW-19B/C. The location of each monitoring well is shown on Figure 3-1.

A summary of monitoring well information, including the well designation, date installed, screened interval, total depth of the boring, and the elevation of the top of each well riser (in ft above the North

American Vertical Datum of 1988 (NAVD88)), is provided in Table 3-4. The construction details for each well are shown on the respective soil boring logs in Appendix D, and on the cross-sectional views discussed in Section 4.

3.2.6 Well Development

Following a minimum 24-hour wait period after well installation, each of the RI monitoring wells was developed in order to remove fine-grained sediment and fluid residue from the well and the sand pack and to create maximum well efficiency. A surge-and-pump method was used to develop the wells. The surging action was used to actively agitate the water column by forcing water back and forth through the well screen and sand pack. Following surging, the wells were pumped with a submersible pump. Wells were developed until turbidity readings were below 50 nephelometric turbidity units (NTU) or a minimum of ten well volumes was removed. Well development equipment was decontaminated between locations in accordance with field procedures in the RIWP. Well development water was containerized in 55-gallon drums for off-site disposal (see Section 3.2.15 for IDW details). A copy of the well development logs is provided in Appendix F.

Following development, wells were allowed to recover for at least 14 days before groundwater was purged and sampled.

3.2.7 Groundwater Monitoring

3.2.7.1 Depth-to-Water Measurements

Groundwater level measurements were collected using an electronic oil/water interface level indicator fitted with a weighted cord, accurate to 0. 01 ft. Depth to water was measured from the surveyed elevation mark on the well riser. The water level indicator was decontaminated between measurement locations in accordance with field procedures in the RIWP. Depth to water measurements and calculated groundwater elevations are provided on Table 3-5. Groundwater contour maps and a discussion of the data are provided in Section 4. Depth to NAPL and NAPL thickness measurements are presented in Table 3-6.

Groundwater monitoring was conducted during the RI program in several phases:

- December 11, 2009 – Static groundwater gauging event prior to a round of groundwater sampling.
- January 12, 2010 – Static groundwater gauging event to support understanding of groundwater flow.
- December 12, 2012 (2 rounds) –Groundwater gauging events corresponding with high and low tides in the English Kills tributary of Newtown Creek.
- February 12, 2013 – Static groundwater gauging event prior to a round of groundwater sampling.
- July 31, 2013 – Static groundwater gauging event prior to a round of groundwater sampling.
- July 16, 2015 – Static groundwater gauging event at existing/accessible monitoring wells, no groundwater samples collected.
- December 4, 2015 – Static groundwater gauging event at existing/accessible monitoring wells, no groundwater samples collected.

Monitoring wells gauged in each event generally included on-Site and off-Site wells installed for the RI and select wells installed by others at surrounding properties (e.g., wells on the Greenpoint Energy Site).

3.2.7.2 Groundwater Sampling

Wells were developed (as described in Section 3.1.6 above) and allowed to stabilize for a minimum of two weeks prior to the low-flow groundwater sampling events. Groundwater sampling was conducted on four occasions (December 2009, August 2012, February 2013, and July/August 2013) during the RI field program, as listed in Section 3.1 above.

Samples were collected using low-flow purging and sampling techniques. Peristaltic pumps were used for purging and sampling each well. Pump intakes were set at the midpoint of the saturated screened interval. Water levels were monitored during purging using an electronic oil/water interface indicator. Flow rates ranged from 200 to 400 milliliters per minute (ml/min). Groundwater was pumped through a flow-through cell during purging, and pH, specific conductivity, temperature, dissolved oxygen (DO), and oxygen reduction potential (ORP) were measured. Turbidity was measured using a separate meter. Parameter measurements were recorded after the flow-through cell was full and approximately every five minutes thereafter. Purging was complete and sampling began when three consecutive readings were within the stabilization parameters as specified in the RIWP and as indicated on the groundwater sample collection records. Prior to sample collection using a peristaltic pump, the flow-through cell was disconnected.

A groundwater sample was also collected from the on-Site pumping well (PW-1). The existing submersible pump in this well was turned on and purged for approximately 5 gallons and a grab sample was collected and analyzed as indicated on Table 3-1. The flow rate of this pump did not allow for low-flow purging prior to sample collection, but given the active pumping of this well at the time the sampling was conducted, the sample is considered to be representative of aquifer conditions. Field parameters were recorded during purging to the extent practicable.

In addition, two groundwater grab samples were collected from SB-14 and SB-20J. Boring SB-14 was located outside and downgradient of the former No. 1 Relief Holder. A grab sample was proposed instead of installation of a monitoring well because of the heavy truck traffic on this parcel that would quickly damage or destroy the well. The sample was collected using a direct-push screen point sampler positioned approximately 10 to 15 ft bgs consistent with the proposed shallow well depths. A sample of the water in the borehole was collected using a peristaltic pump connected to the down-hole screen point sampler following the general methods described in Section 3.2.7.1 above. Boring SB-20J was installed near the on-Site pumping well, PW-1, into bedrock. The intent was to identify the Jameco Gravel, if present, and locate a potential productive zone for groundwater pumping to replace PW-1. The sample was collected from within the borehole at an approximate depth of 80 ft bgs. The groundwater grab samples were analyzed for the parameters listed in Table 3-1.

In total, 40 groundwater samples (not including field duplicate samples) were collected and analyzed for the parameters listed in Table 3-1. The majority of the groundwater samples were analyzed for the following parameters:

- VOCs by USEPA Method 8260B
- SVOCs by USEPA Method 8270C
- TAL Metals by USEPA Method 6000-7000 Series

- Total cyanide by USEPA Method 9012

Groundwater samples from off-Site well clusters M-16A/B/C, M-17A/B/C, M-18A/B/C, and M-19A/B/C were not analyzed for metals. A subset of samples was analyzed for PCBs (as Aroclors) and TCL pesticides and TCL herbicides.

Purge water was stored in 55-gallon drums later for off-site transport and disposal (see Section 3.2.15 for IDW details). Decontamination of equipment was not necessary as disposable materials were used to collect the samples. Sample details including sample date(s) and laboratory analysis are summarized on Table 3-1. A copy of groundwater collection records are provided in Appendix G. Analytical results are discussed in Section 5.

3.2.8 Hydraulic Conductivity Testing

On January 12 and 14, 2010 hydraulic conductivity testing was performed at seven wells: MW-2A and MW-4A (shallow zone wells); MW-2B and MW-4B (intermediate zone wells); and MW-1C, MW-3C, and MW-4C (deep zone wells).

Solid slug test methods were used for shallow well MW-4A which was screened across the water table and pneumatic test methods were used for MW-2A and the intermediate and deep wells screened below the water table. Slug test data was analyzed using AQTESOLV® software produced by HydroSOLVE, Inc. Rising-head data were matched against the Bouwer-Rice solution (Bouwer and Rice, 1976) for unconfined aquifers using the straight-line fitting method. The AQTESOLV® output files, including graphs of the fitted lines are provided in Appendix H.

Results of the hydraulic conductivity testing and continuous water level monitoring are discussed in Section 4.

3.2.9 Tidal Monitoring

On January 12 through 14, 2010 (concurrent with the hydraulic conductivity testing discussed above), continuous water level measurements were collected during a 24-hour period to evaluate potential tidal effects on water levels. Measurements were collected at nine locations: MW-1A, MW-1B, M1-C, MW-2A, MW-02B, MW-3C, MW-4A, MW-4B, and MW4-C.

Results of the tidal water level monitoring are discussed in Section 4.

3.2.10 DNAPL Baildown Testing

DNAPL baildown testing was completed on select wells containing DNAPL to inform the RI and to provide data to better understand DNAPL behavior and recoverability and migration potential. On March 12, 2010, DNAPL baildown tests were successfully initiated at wells PW-1 (Cooper Tank's former dust suppression well) and MW-3B (Figure 3-1), which had initial DNAPL thicknesses and volumes of 2.61 ft and 5.18 ft, respectively. In February 2012, DNAPL recovery tests were performed at wells MW-14B and MW-15B, which had initial DNAPL thicknesses of 6.38 ft and 10.15 ft, respectively. During purging slightly more than the total effective well volume (volume within the well casing plus pore space in the sand pack) was removed from each well. Following the removal of DNAPL from these wells, the wells were gauged periodically to assess the rate of DNAPL recovery in each well.

DNAPL recoverability potential is dependent on other factors including the DNAPL head, DNAPL extent, proximity of receptors, Site hydraulic gradient, DNAPL properties, and soil parameters. Additional data regarding these Site parameters was also collected to support the recoverability evaluation. For example, DNAPL and water samples were collected from MW-3B, MW-15B, and PW-1 and sent to Torkelson Geochemistry, Inc. for analysis of viscosity, density, and interfacial tension. Results of the testing are discussed in Section 5.5.

3.2.11 Community Air Monitoring

Community air monitoring was performed to provide real-time measurements of total VOCs and particulate (airborne dust) concentrations in air at the downwind perimeter of each designated work area when intrusive investigation activities were in progress in the RI Study Area. The procedures followed methods described in the CAMP (RIWP Appendix E). Additionally, Site personnel monitored the perimeter stations to determine if any odors were being produced as a result of the intrusive sampling activities. The monitoring was designed to provide protection for the downwind community, such as those present at the adjacent public areas and commercial properties, from releases of fugitive emissions potentially resulting from the investigation activities.

Total VOCs and particulates were monitored with a PID and a particulate meter, respectively, located upwind and downwind of each work zone. The VOC and particulate levels at each location were recorded on field forms every 15 minutes, and are included in Appendix I. The PIDs and particulate meters were also set to log information continuously throughout the work day. This information was downloaded to a laptop computer so that the NYSDEC and NYSDOH could review the information if needed. The specific action levels for VOCs and particulates are provided in the CAMP. Action levels were not reached as a result of the intrusive investigation activities at any time during the RI and associated addendums, so no response actions were necessary

3.2.12 Vapor Intrusion Evaluation Sampling

Vapor intrusion sampling was conducted at four properties on/adjacent to the Site over five events in 2009, 2010 (two events), 2011, and 2015. Four rounds of samples were collected from 222 Maspeth Ave, two rounds were collected from 252 Maspeth Ave, and one round was collected from both 1 Rewe Street and 7-9 Rewe Street. At each location a pair of sub-slab vapor and indoor air samples was collected, along with one outdoor ambient air sample per event. Table 3-2 lists the samples collected in each event, and Figure 3-1 shows the sampling locations.

At 222 Maspeth Ave, the samples were collected from the ground floor (locker room area) of the office structure. At 252 Maspeth Ave, the samples were collected from the ground floor of the mechanics shop. In the building at 1 Rewe Street, two sets of samples were collected from different ends of the building, and at 7-9 Rewe Street, one set of samples was collected from the north end of the building.

Prior to conducting the sampling, utilities were cleared by geophysical methods as described in Section 3.2.1 above. In addition, a chemical inventory was conducted within the building locations, along with completion of the NYSDOH indoor air quality questionnaire and building inventory form (Appendix J).

Once utilities were cleared, sub-slab soil vapor samples were collected immediately below the concrete floor slabs. Sampling implants were installed by drilling a ¾-inch diameter hole through the slab and placing Teflon® tubing in the hole. An air-tight seal was created by filling the space between the tubing and the concrete with hydrated bentonite. The tubing used for sampling was attached to a

sampling canister with Swagelok™ fittings. A helium-filled “shroud” was placed around the insertion points to confirm the integrity of the seals. One to three volumes of air were then purged from the tubing with a helium meter at a rate less than 0.2 liters per minute. During sampling activities, no helium was detected indicating that no leaks were found in the seals for each location. Once the seals were checked, the samples were collected in batch certified, 6-liter Summa canisters fitted with eight-hour regulators. Following sample collection, all concrete coring holes were sealed and patched to match the existing grade.

The indoor air samples were also collected at the same locations as the sub-slab soil vapor samples. One ambient air sample was collected during each event at a location upwind of the buildings at the time of sampling. These samples were collected using individually certified, 6-liter Summa canisters fitted with eight-hour regulators.

Decontamination of equipment was not necessary as disposable materials were used to collect the samples.

All samples were shipped via an overnight courier to a NY ELAP-certified laboratory for analysis. Sub-slab soil vapor, indoor air, and ambient air samples were analyzed for VOCs (including naphthalene) by USEPA Compendium Method TO-15. The soil vapor samples were also analyzed for helium using ASTM Method D-1945 Modified and a specific MGP indicator compound list provided by National Grid. Sample details including sample identification, sample date(s), and laboratory analysis are summarized on Table 3-2. Analytical results are discussed in Section 6.

3.2.13 Analytical Program

The laboratory samples for each media and the chemical analyses performed are summarized in Tables 3-1 and 3-2. Requisite quality assurance/quality control (QA/QC) samples were collected and analyzed in accordance with the QAPP. The laboratory analysis during the RI and PDIs was completed by the following laboratories:

- H2M Labs, Inc. of Melville, NY – Initial RI, August 2010 IA/SV and February 2011 IA/SV sampling
- Air Toxics, Ltd. of Folsom, CA – March 2010 IA/SV sampling
- TestAmerica Laboratories, Inc. of Edison, NJ – RI Addendum No. 1, RI Addendum No. 2, RI Addendum No. 4
- Spectrum Analytical, Inc. of Warwick, RI – RI Addendum No. 1 and PDI for Shallow Soil Removal
- Accutest Laboratories of Marlborough, MA – RI Addendum No. 2 Modification, RI Addendum No. 3

Soil analytical methods included the following:

- VOCs - USEPA Method 8260
- SVOCs - USEPA Method 8270
- Metals - USEPA Method 6000-7000 Series
- PCBs as Aroclors - USEPA Method 8082

- Free Cyanide - extraction by EPA Method 9013A and analysis by Microdiffusion, ASTM International Method D4282-02
- Pesticides - USEPA Method 8081
- Herbicides - USEPA Method 8151
- Total Petroleum Hydrocarbons (TPH) - GC/FID by EPA Method 8015

Groundwater analytical methods included the following:

- VOCs - USEPA Method 8260
- SVOCs - USEPA Method 8270
- Metals - USEPA Method 6000-7000 Series
- PCBs as Aroclors - USEPA Method 8082
- Total Cyanide – USEPA Method 9012
- Pesticides - USEPA Method 8081
- Herbicides - USEPA Method 8151

Indoor air, soil vapor, and ambient air analytical methods included:

- VOCs (including naphthalene) - USEPA Compendium Method TO-15 (note that in addition to the standard TO-15 list of compounds, several additional compounds were analyzed including indane, indene, thiophene, styrene, 2-methyl pentane, isopentane, 2,3-dimethyl pentane, isooctane, and methyl tert-butyl ether (MTBE)
- Helium - ASTM Method D-1945 Modified

3.2.13.1 Quality Assurance/Quality Control Analyses

Field and laboratory quality control samples for the investigation were collected and analyzed to document the accuracy and precision of the sample results. The QA/QC samples included trip blanks, field duplicates and matrix spikes (MS), and matrix spike duplicates (MSD). The data quality level for the investigation was Level IV and was consistent with reporting requirements outlined in the NYSDEC Analytical Services Protocol (ASP) July 2005 methodologies. Full ASP Category B data packages will be prepared by the laboratory for all samples collected during the RI, and are included in Appendix K.

3.2.13.2 Data Usability Summary Report

For quality control purposes, comprehensive CLP-equivalent data packages were produced by the various laboratories for the soil, groundwater, soil vapor, and indoor air samples for review by a qualified chemist. A USEPA Region II data usability summary report (DUSR) was prepared by the AECOM Environmental Chemistry Group for each soil and groundwater sampling event. The DUSRs for this project are included in Appendix L.

As part of the data review process, analytical results and data qualifiers were corrected, where necessary, to reflect quality control issues. The Form I Report Sheets in Appendix L and the data

summary spreadsheets discussed in this section includes the data qualifiers and reflects the findings of the data validation process.

Organic data quality was evaluated by reviewing the following parameters: holding times, GC/MS tuning and performance, internal standards, initial and continuing calibrations, surrogate recoveries, MS/MSD samples, MS/MSD relative percent differences (RPDs), laboratory control standards (LCSs), laboratory blanks, laboratory and field duplicates, compound identification, and compound quantitation.

Inorganic data quality was evaluated by reviewing the following parameters: holding times, matrix spikes, initial and continuing calibrations, contract required detection limit (CRDL) standard recoveries, laboratory control samples, ICP interference check sample results, ICP serial dilution results, laboratory and field duplicates, and laboratory blanks, and analyte quantitation.

3.2.14 RI Study Area Survey

Following completion of each phase of investigation, all boring, test pit, and monitoring well locations were surveyed for location, ground surface elevation, and top of casing elevation and measuring point elevation for monitoring wells, using a licensed New York surveyor. In addition, other property elements such as property boundaries, topography, and Site features were surveyed as needed. All horizontal locations were reported in the New York State Plane Coordinate System, Long Island Zone (NAD83) in ft. All vertical measurements were reported in ft relative to NAVD88.

3.2.15 Investigation-Derived Waste Management

In addition, during each investigation phase, all Investigation Derived Waste (IDW) generated was collected in properly labeled USDOT-approved storage containers (55-gallon drums) or small bulk roll-off containers and grouped by environmental matrix (soil, water, PPE/plastic, construction debris). The drums (or roll-off containers) were stored within the 254 Maspeth Avenue parcel in a temporary storage area.

Subsequently, the waste was characterized with laboratory analyses including full TCLP, corrosivity, ignitability, reactivity, TPH, and PCBs. Waste transportation and disposal of all contaminated wastes was managed by National Grid in accordance with management of IDW procedures outlined in the FSAP provided in the RIWP (AECOM, 2009).

4.0 Geology and Hydrogeology

4.1 RI Study Area Geology

RI Study Area geology and stratigraphy were developed based on observations of soil from the test pits and soil borings completed during the RI, as well as observations from previous investigations at in the RI Study Area. Soil boring and test pit logs are included in Appendices D and E, respectively. Based on the information presented in these logs and previous investigations, seven stratigraphic cross-sections were generated. The orientation of the cross-sections, shown on Figure 4-1, were positioned to present representative “slices” of the subsurface within the investigation area on-Site, as well as off-Site at 300 Maspeth Avenue, Greenpoint, and at 1 and 7-9 Rewe Street. Individual sections are provided on Figure 4-2 (A-A’), Figure 4-3 (B-B’), Figure 4-4 (C-C’ and D-D’), Figure 4-5 (E-E’ and F-F’), Figure 4-6 (G-G’) and Figure 4-7 (H-H’).

As shown on the cross sections, site specific observations are consistent with regional geology presented in Section 2.4. The RI Study Area stratigraphy is dominated by five primary units:

- anthropogenic fill
- meadow mat consisting of fibrous and friable peat, organic silts and clay, and marine clays
- glacial-outwash and fluvial deposits consisting of sands and silts often interbedded, as well as gravels
- glacial-lacustrine deposits consisting of silts and clays
- the Gardiners Clay, a regional confining unit

These units are part of the upper Pleistocene and recent Holocene regional deposits. Within the sand/silt unit are continuous and discontinuous lenses of sand, silts, and clay. These units have been assigned to the following site-specific formations named to support the RI:

- Fill
- Sand
- Meadow Mat
- Intermediate Sand
- Intermediate Clay
- Lower Sand
- Lower Clay
- Gravelly Sand
- Gardiners Clay (Regionally Defined)

These units are described in detail in the following sections.

One soil boring, SB-20J, was advanced to bedrock, which was encountered at 192.0 ft bgs. This boring was advanced into bedrock to a final depth of 250 ft bgs. The Gardiners Clay was present overlying bedrock at this location, and no identifiable Jameco Gravel unit was encountered. The lack of the Jameco Gravel unit beneath the RI Study Area is consistent with data presented in by Buxton and Shernoff's (1999) hydrostratigraphic descriptions showing the northern extent of the Jameco Gravel in the vicinity but south of the RI Study Area. Therefore, the Gardiners Clay was the deepest non-consolidated overburden unit encountered during the RI.

4.1.1 Fill

As shown on the cross-sectional views, fill was observed to be present in all areas of the RI Study Area in thicknesses typically ranging from 15 to 25 ft, and within the range of the groundwater table. The fill is comprised of mostly poorly graded sand, silt, and gravel with varying amounts of anthropogenic material: coal fragments, ash, concrete slabs, wood pieces, wood fragments, brick fragments, and glass. Other urban fill debris including carpeting and metal scraps consistent with the Site's most recent use as a waste transfer station, were encountered at 222, 252, and 254 Maspeth Avenue.

4.1.2 Sand

In a few isolated locations, a fine sand unit with little silt was observed above the meadow mat, and represented post glacial deposition. The thickness of the unit is less than 10 ft. These units were encountered beneath 222 Maspeth Avenue at SB-20J, along the northeastern Site boundary at PDI-3, and off-Site to the south beneath 7-9 Rewe Street at SB-45.

4.1.3 Meadow Mat

As shown on cross-sectional views, a layer of meadow mat (peat and clay) was observed to be present in all areas of the RI Study Area underlying fill in thicknesses typically ranging up to 4 to 20 ft with thickness generally increasing with proximity to the English Kills tributary of Newtown Creek. The meadow mat represents the former ground surface prior to development (filling) in the RI Study Area and is mostly continuous, which is consistent with the historic marshy environment of this area (see Figure 4-8). However, this unit was likely completely excavated within the footprint of the No. 1 Gas Holder at 222 Maspeth based on the total depth of the holder exceeds the bottom of the meadow mat observed in the closest borings, and may have been partially excavated at other locations prior to or during the filling of the area to industrial development of the area.

The meadow mat consists of varying amounts of a densely compacted decomposed vegetative material (peat), organic clays, marine clays with shell fragments, and silt, and is brown/tan or grey in color with a distinctive organic-like odor. The unit acts to separate the underlying native soils from the overlying fill.

4.1.4 Intermediate Sand

Between the bottom of the meadow mat and the top of the Gardiners Clay, are units of glacial outwash dominated by sands and silts. The shallower formation of this unit is the Intermediate Sand. The unit varies in composition, occurring as tan and grey interbedded sand and silt beds and as well graded to poorly graded sands and silt zones. With depth, the percentages of fines tend to increase until a sharp transition to dense, hard clay with silt and sand lenses, hereafter "interbedded clay", as described below. This layer ranges from five to twenty ft thick, was generally encountered 20 ft to 30 ft bgs.

4.1.5 Intermediate Clay

This interbedded clay unit, labelled the “Intermediate Clay” unit in the RI Study Area, is present within the Upper Pleistocene glacial outwash deposits and tends to be around 20 ft thick in most areas of the RI Study Area. The Intermediate Clay unit pinches out beneath western parts of the 222 Maspeth Avenue, 1 Rewe Street, and the Greenpoint Energy Center properties. This clay unit represents a localized confining layer beneath the RI Study Area where present. This layer ranges from 19 to 35 ft thick, was generally encountered 36 ft to 52 ft bgs. The topography of the top of the intermediate clay unit is presented on Figure 4-9.

4.1.6 Lower Sand

Beneath the Intermediate Clay unit is another sequence of Upper Pleistocene glacial outwash deposits comprised of interbedded sands and silts described as the “Lower Sand” unit. These deposits were documented in all borings beneath the RI Study Area below the Intermediate Clay unit, beneath the Lower Clay unit, and in areas where the Intermediate Clay unit was absent. This layer ranges from 5 to 10 ft where the intermediate and the low clay units are present to 40 ft thick along the western side of the Site. The top of the unit was generally encountered between 46 ft to 80 ft bgs.

4.1.7 Lower Clay Lens

A clay lens labelled the “Lower Clay” lens was identified in several borings within the Lower Sand unit, primarily beneath the 222 and 252 Maspeth Avenue parcels. This lens acts as a localized confining layer where present. Where present, this unit ranges from 5 to 10 ft thick, was generally encountered between 78 to 86 ft bgs. The topography of the top of the lower clay lens unit is presented on Figure 4-10.

4.1.8 Gardiners Clay

The Gardiners Clay is present beneath all areas of the RI Study Area that were investigated at typical depths of 85 to 100 ft bgs. Lignite is present at the top of the Gardiners Clay at select borings. The presence of lignite is consistent with regional descriptions provided by Buxton and Shernoff (1999). The unit is comprised of a high plasticity, stiff, blue to greenish gray clay and silty clay. At one boring, SB-20J, the Gardiners Clay was observed to be approximately 80 to 100 ft thick (Appendix E). The Gardiners Clay is consistent in depth and composition with regional descriptions provided by Buxton and Shernoff (1999) and Misut and Monti (1999). The unit represents a confining unit defining the lower extent of the Upper Pleistocene glacial deposits aquifer. The topography of the top of the Gardiners Clay unit is presented on Figure 4-11.

4.1.9 Bedrock

Competent bedrock was encountered at one soil boring, SB-20J, at a depth of 192.0 ft bgs. From approximately 192 to 197 ft bgs, bedrock fractures were observed to be filled with Greenish grey clay. This boring was advanced into bedrock to a final depth of 250 ft bgs. The bedrock was comprised of schist identified as the Hartland Schist on the Bedrock and Engineering Geologic Map of New York County and Parts of Kings and Queens Counties, New York (USGS, 1994). There was an observed weathered saprolite zone in the upper 15 ft of bedrock starting at 177 ft bgs showing relic bedrock structures. In general, the bedrock is relatively impermeable, with water transmitted along faults and fractures.

4.2 Site Hydrogeology and Groundwater Flow

Prior to urbanization, fresh water recharge would have been entirely through precipitation (rain or snowfall). It is estimated that 50% of annual rainfall (44 inches per year average) was recharged to groundwater; the remaining would have gone to evapotranspiration and direct runoff. Currently, as a result of the land use changes that include large expanses of paved and impervious surfaces, it is estimated that only 15% of precipitation enters the groundwater through recharge in Kings County (Buxton and Shernoff, 1999). The Site and the area around the Site is relatively impervious and therefore it is expected that this rate is appropriate for the Site itself.

Aquifer (slug) testing was completed on-Site to estimate hydraulic conductivities. The results of the analysis of these tests are summarized on Table 4-1. The hydraulic conductivities of the fill materials at MW-2A and MW-4A ranged over two orders of magnitude from 2.16 to 143.7 ft per day (ft/d). This is expected since the nature of the fill was variable and the way in which it was placed is not expected to have been systematic or regulated. The hydraulic conductivity of the intermediate soils (sand and silt) beneath the peat/clay confining unit was calculated to be 1 ft/d at MW-4B and 4 ft/d at MW-2B. This range is consistent with what is expected for these soil types (Freeze and Cherry, 1979). The hydraulic conductivities for the deepest soils ranged from 7 ft/d to 50 ft/d. This range reflects the varying percentages of finer-grained soils observed in RI Study Area borings.

Groundwater contour maps (Figures 4-12 through 4-17) have been prepared for the shallow, intermediate, and deep groundwater zones for two rounds of data (December 11, 2009 and December 4, 2015). Table 3-5 presents the measured groundwater elevations for the RI Study Area. Table 4-2 shows the calculations of horizontal gradient, and Table 4-3 summarizes vertical gradients.

4.2.1 Shallow Zone Wells

The water table was generally encountered in the RI Study Area at 6 to 10 ft bgs. There is a groundwater elevation difference between the shallow water levels and the intermediate water levels indicating downward gradients from the shallow to intermediate zone wells (Table 4-3). There are no Site-specific data to characterize hydraulic conductivity of the meadow mat unit located between the shallow and intermediate zones, but it is expected to be at least two orders of magnitude lower than the conductivities for either the shallow or intermediate zones. Despite the strong downward vertical gradients in shallow zone wells, groundwater flow in the shallow zone wells in December 2015 was to the south-southeast (Figure 4-13).

4.2.2 Intermediate Zone Wells

Within the intermediate zone, groundwater elevations tend to be higher in the western portion of the RI Study Area, and lower to the east and south (Figures 4-14 and 4-15). Groundwater elevation data at MW-6B however do not fall into this pattern. The lower elevations in this well are interpreted to be the result of groundwater pumping at the Brooklyn Truck Wash property located at 184 Maspeth Avenue from a depth consistent with the screened interval of the intermediate zone wells. This interpretation is supported by pressure transducer data collected from wells MW-1B and MW-1C (near MW-6B) during tidal influence monitoring that showed a pattern of variable water levels over time consistent with groundwater pump cycling (see Section 4.2.5 below). Groundwater flow direction in the intermediate zone is also consistent with that observed at the neighboring Greenpoint Energy Center Site.

Horizontal groundwater gradients in the intermediate zone based on the contours shown on Figures 4-14 and 4-15, are calculated to range between 2.15E-3 ft/ft and 1.22E-2 ft/ft depending on the flow path. Assuming a hydraulic conductivity of 2.4 ft/d (average hydraulic conductivity value for MW-2B and MW-4B, Table 4-1) and a porosity of 0.25, groundwater velocities range between 7.5 and 43 ft per year in the intermediate zone.

4.2.3 Deep Zone Wells

Below the interbedded clay in the deep groundwater wells, groundwater flow towards the south-southeast (Figures 4-16 and 4-17). This flow direction is consistent with the intermediate zone wells and flow directions observed at the neighboring Greenpoint Energy Center Site at similar depths. Horizontal groundwater gradients are calculated to range between 9.88E-4 ft/ft and 6.43E-3 ft/ft depending on the flow path (Figures 4-16 and 4-17). Given the range of hydraulic conductivity calculated and assuming a porosity of 0.25, groundwater velocities range from 2.4 to over 22.5 ft per year within this interval.

The groundwater pressure head potential calculations are set forth in Table 4-3. While the vertical hydraulic head potential in the deep zone is greater than in the intermediate zone in certain areas (MW3B/C and MW-4 B/C), the presence of the low conductivity intermediate clay unit separating the intermediate zone and deep zone should impede actual groundwater flow between these zones. Furthermore, there is no indication that groundwater flows from the intermediate zone to the shallow zone based on gauging data.

4.2.4 Groundwater Flow Summary

Flow in the shallow fill zone is controlled predominately by the peat/clay layer and the small amount of recharge that comes via precipitation. Other local controls on the flow in the shallow zone may be the result of infrastructure, such as utilities located beneath Maspeth Avenue which may act as sources or sinks of water to the groundwater system. The regional boundary conditions (rainfall recharge and surface water discharge) also have control over the intermediate and deep zone flow. In shallow and intermediate depth aquifer zones, flow is generally horizontal to east-southeast toward English Kills. Beneath the RI Study Area, the Gardiner's Clay acts as a confining unit between the overburden above it and the bedrock below.

There are measurable vertical head potential differences between the shallow and intermediate, and between the intermediate and deep groundwater zones, as outlined on Tables 4-2 and 4-3. Data also suggest a component of upward head potential between the deep and intermediate aquifer zones that is likely related to the confining nature of the intermediate clay unit, to the proximity of the English Kills discharge boundary, or some combination of both. As stated above, both Site specific and regional data indicate that overall groundwater flow is from approximately west to east-southeast.. Data from the deepest wells on-Site best represent the regional flow conditions. On a regional basis, given that the Upper Glacial Aquifer (UGA) beneath the site is over 100 ft thick and that the English Kills represents the upper reach of an estuarine system of Newtown Creek, it is likely that some portion of deep groundwater flow beneath the Site underflows the English Kills/Newtown Creek system and discharges more directly to the regional East River discharge boundary. For purposes of this RI however, it was not necessary to evaluate the portion of the deep aquifer zone that may underflow English Kills.

4.2.5 Tidal Influence

The influence of the surface water boundary conditions on the deep groundwater levels is most evident when looking at the tidal impacts. Figure 4-18 shows water levels recorded over two days at several on-Site wells and compares them to tidal data at a nearby tidal monitoring station. Shallow and intermediate wells were not impacted by tides, but deep groundwater levels at MW-3C and MW-4C were clearly related to the tidal cycle. The lack of response in the shallow and intermediate zones indicates that there is a poor hydraulic connection between the deep zone and overlying zones. Groundwater levels at MW-1C were not impacted by tidal changes even though this well is screened at a similar depth as that at MW-3C and MW-4C. This difference is attributed to the lack of overlying interbedded clay unit in this area. The clay elsewhere acts to confine the deep groundwater zone, thus allowing the pressure wave from the tidal change to be represented and recorded in those areas. In the absence of the clay, the tidal impacts are not as apparent because the deep groundwater is not pressurized. The small (a few tenths of a foot) fluctuations in water levels seen at MW-1B and MW-1C are attributed to pumping at the Brooklyn Truck Wash property (184 Maspeth Avenue), located on the west side of Vandervoort Avenue.

5.0 Subsurface Environmental Observations and RI Analytical Results

This section presents a summary of subsurface field observations and the results of the laboratories analyses performed for the RI samples. A discussion of the results of the analyses, and a comparison to applicable NYSDEC Standards, Criteria and Guidance Values are grouped according to environmental media in the sections following the description of observed subsurface conditions. NYSDEC ASP Category B data packages were prepared by the laboratory for all samples collected during the RI and are included in Appendix K.

5.1 Observed MGP Structures

Two former MGP structures were encountered during the RI. These are shown on Figure 5-1, and include the 430,000 cu ft No. 1 Relief Holder/Storage Holder No. 1 located at 222 Maspeth Avenue, and the No. 1 and No. 2 Oil Tanks at 254 Maspeth Avenue. Soil borings SB-8 and SB-13 were installed within the footprint of the Relief/Storage Holder. Fill materials consisting of sand, gravel, wood, slag, and trace ash were encountered from below the concrete surface slab of the waste transfer facility to the distinct split-spoon refusal depths of 26 ft and 25.5 ft bgs at SB-8 and SB-13, respectively. Based on constructions drawing provided by BUG, included in Appendix B, the former No. 1 Relief Holder depth along the circumference is 33 ft bgs. The boring refusals likely represent the center mound of the holder. This configuration is shown on cross-sections A-A' and B-B' on Figures 4-2 and 4-3. Impacts are present within the holder and include staining and sheens, as well as NAPL saturated intervals and lenses with naphthalene-like odors within the bottom 10 ft of the holder. Additional detail is presented on Table 5-1 and on the borings logs available in Appendix D.

Test pit TP-2 was excavated in an "L" shape across the No. 1, No. 2 and No. 3 Oil Tanks at 254 Maspeth Avenue. A section of concrete slab was encountered at 8 ft bgs beneath the eastern half of the TP-2 in the approximate location of the No. 1 and No. 2 Oil Tanks and Oil House. Fill materials of sand, gravel, and brick and concrete fragments were encountered above the slab, with pockets of black viscous NAPL and solidified NAPL with a strong naphthalene-like odor. The water table was encountered at approximately 8 ft bgs, and contained some oil-like material with a yellow tint and a fuel-oil like odor. The location of the Oil Tanks is shown on Figure 5-1.

5.2 Summary of Visible and Olfactory MGP and Petroleum Related Impacts

Visible and olfactory impacts of residual NAPL with naphthalene-like odors and petroleum related materials observed in the subsurface are summarized on Tales 5-1 and 5-2, shown on the cross-sections A-A' through H-H' (Figures 4-2 through 4-7), and illustrated in plan-view on meadow mat and clay contours on Figure 5-2 through 5-5, as well as on the boring logs provided in Appendix D. Table 5-1 summarizes visible and olfactory impacts observed in soil borings, monitoring wells, and test-pits advanced during the RI, PDIs, and IRMs. Visible impacts, including staining, sheen and the presence of NAPL can be evidence of environmental impacts from the MGP as well as from a number of the other non-MGP industrial sources that have been identified in the RI Study Area. Table 5-2 summarizes visible and olfactory impacts observed in soil borings and monitoring wells installed by others prior to the RI in the RI Study Area and at 300 Maspeth Avenue. Impacts are grouped into a color categories provided in NYSDEC MGP field descriptor guidance. These categories are defined

on the tables and figures, and include odors (subjectively qualified as petroleum-like or naphthalene-like by the field geologist), staining, blebs and globs and sheens, coated material or lenses, and NAPL saturated. Zones of NAPL saturation represent areas where the entirety of the pore space of the soil matrix appears to be filled with NAPL.

As discussed in Section 4.1, the RI Study Area stratigraphy includes four low permeability units, which include a meadow mat, an intermediate clay unit that pinches out to the west below the No.1 Relief Holder, a lower clay unit that also pinches out pinches out to the west below the No.1 Relief Holder and to the east beneath the 254 Maspeth Avenue parcel, and the Gardiners Clay that is laterally continuous regional confining later beneath the RI Study Area. As shown on the meadow mat and clay contour figures (Figures 5-2 through 5-5) and the cross-sections (Figures 4-2 through 4-7), NAPL saturated zones are primarily encountered within the bottom 10 ft of fill above the meadow mat (generally 14 to 25 ft bgs), and in the permeable interbedded sands and silts above the intermediate clay. The zones of complete NAPL saturation typically range from half a foot to 2 ft in thickness. However, due to the interbedded nature of the sands and silts above the intermediate clay, NAPL occurs predominately in thin sand lenses from half an inch to 3 inches thick. Associated with these saturated NAPL lenses are moderate to strong naphthalene-like odors. A few, less extensive NAPL saturated lenses are also present on the lower clay below the RI Study Area, and on the Gardiners Clay in areas where the intermediate clay and lower clay lenses are absent.

As shown on Figure 5-2 and summarized on Table 5-1, visible NAPL related impacts are present in the fill and the few sand units above the meadow mat, and in the interbedded silts and sands and gravelly sands that are present between the low permeability clay units. During the RI, NAPL was encountered at depths ranging from 4.3 ft bgs (8.36 ft NAVD88) at SB-12A to 92.5 ft bgs (-79.86 ft NAVD88) at SB-22.

5.2.1 Above and Within the Meadow Mat

Solidified NAPL with a naphthalene-like odor was observed as hardened pockets and pieces within the fill at depths ranging from the ground surface (TP-2) to 10 ft bgs where a trace amount was observed at SB-15. Thicknesses of the pockets ranged from 0.15 ft at TP-2 to 2 ft at SB-4 and TP-4. The solidified NAPL was encountered primarily beneath the southwest area of the 254 Maspeth Avenue property, as well as at an isolated location (SB-15) along the eastern boundary of the 252 Maspeth Avenue property. Much of this material was removed during the shallow soil IRM. See Section 6 for more details.

As shown on Figure 5-2, NAPL impacts of petroleum-like odors, sheens, and staining were also observed within the fill materials beneath the eastern end of the 254 Maspeth Avenue property. Petroleum saturation and sheens were also observed to the west of the Site along Vandervoort Avenue at SB-6B near the location of oil releases observed during utility pole replacements and excavations (Spill No. 0701343; Spill No. 0701344, and Spill No. 0705958; AECOM 2009). Impacts were also observed to the southeast of the Site beneath 7-9 Rewe Street and 300 Maspeth Avenue. Depths to NAPL staining and sheens ranged from 4 ft bgs at SB-7A (8.51 ft NAVD88) to 27 ft bgs (-12.92 ft NAVD88) at SB-45. A thin layer of NAPL was observed at 8 ft bgs on the water surface during the advancement of TP-2 across the footprint of the former No. 1 and No. 2 Oil Tanks at 254 Maspeth Avenue. See Section 5.1 for additional information. Petroleum odors and sheens were observed coincident with the foot print of the former bulk fuel-oil storage facility located at 7-9 Rewe Street (borings SB-41, SB-45, SB-46, and SB-47). Petroleum odors and sheens were also observed in borings advanced along the eastern property boundary of 300 Maspeth Avenue and to the southeast of the former UST excavation performed by FedEx (See Section 2.10.2).

Above the meadow mat, NAPL impacts were observed beneath most of the Site with the exception of the eastern edge of the 254 Maspeth Avenue parcel (Figure 5-2). Thicknesses of NAPL saturated lenses ranged from 0.1 ft at SB-11 to 5 ft at SB-21, SB-29, SB-30, and PDI-3. Off-Site, NAPL saturated lenses above the meadow mat were limited to two locations (SB-27 at the Greenpoint Energy Center and T1-SB8 at FedEx). NAPL coatings were also noted in nearby adjacent borings in these areas. As shown on Cross-Section H-H', to the north of the Site a 0.4 ft thick saturated NAPL interval was observed at SB-27 from 17.2 to 17.6 ft bgs along the southern boundary of the Greenpoint Energy Center Site. To the north and northeast of SB-27, NAPL impacts consisted of thin bands of NAPL coated material observed in borings SB-28 (12.7-12.9 ft bgs) and GPEC-SB334. NAPL saturation was also observed to the southeast of the Site on the FedEx property at 300 Maspeth Avenue. A 0.5 foot thick interval of saturated NAPL was observed from 18-18.5 ft bgs at T1-SB8. The impacted area is limited in extent; NAPL stringers, coatings, and blebs were observed in borings 15 ft to the north (T1-SB7) and 50 ft to the south (T2-SB1). The remaining impacts along this transect consisted of slight sheens and naphthalene-like odors. To the east, along the eastern FedEx property boundary, trace NAPL coatings were observed in a 0.5 ft interval from 18 to 18.5 ft bgs at one boring (T5-SB2; Figure 5-2). The NAPL coating at the T5-SB2 location is not likely to be mobile or extend significantly beyond this location on the 300 Maspeth Avenue property. The material is in a non-saturated state and no longer has sufficient volume to create the pressure head for further migration (Gusawa and Kueper, 2003). As discussed below, petroleum-like odors and sheens were also observed in this area in proximity to former USTs at the 300 Maspeth Avenue property. To the west of the Site, NAPL observations above the meadow mat consisted of small pockets of NAPL blebs and NAPL coatings from 19.5 to 23.5 ft bgs beneath 1 Rewe Street. Although NAPL saturation was observed above the meadow mat in borings advanced along the northeastern and southern Site boundaries, NAPL was not observed in borings SB-26 at 300 Maspeth Avenue, SB-1C along Vandervoort Avenue, and SB-41 and SB-44 beneath 1 Rewe Street and 7-9 Rewe Street.

5.2.2 Above the Intermediate Clay

As shown on Figure 5.3 and cross-section A-A' and discussed in Section 5.1, NAPL saturation and lenses are present from 4 to 10 ft above the bottom of the No.1 Relief Holder at 222 Maspeth Avenue and in the interbedded sands and silts above the intermediate clay adjacent to, below, and to the to the east of the holder. NAPL saturated lenses above the intermediate clay were encountered from 26 ft bgs (-11.31 ft NAVD88) at SB-5B/MW-5B to 53 ft bgs (-39.39 ft NAVD88) at SB-11. Thicknesses of the NAPL saturated lenses ranged from 0.2 ft at SB-15 to 8 ft at PDI-1. However, entire impact intervals consisting of interbedded silts and sands with impacts ranging from NAPL saturated, to coatings, blebs, and sheens often exceeded 10 ft in borings advanced beneath the Site.

As shown on the intermediate clay contours on Figure 5-3, the majority of the NAPL impacts were observed beneath the Site where the intermediate clay is deepest. Furthermore, NAPL thickness of over 4 ft were measured in monitoring wells MW-3B along the northeastern border of 254 Maspeth Avenue and in wells MW-14B and MW-15B beneath 252 Maspeth Avenue and downslope (following clay surface topography) of the No.1 Relief Holder.

Although NAPL impacts are present along the eastern Site boundary, they do not extend far onto the neighboring FedEx property as shown by the absence of impacts above the intermediate clay at SB-26 and SB-25.

NAPL impacts were observed south of the Site boundary under the 1 Rewe Street and 7-9 Rewe Street properties; however, impacts did not extend to or beyond Rewe Street. NAPL saturated soils were observed from 43 to 48 ft bgs at one boring (SB-43) advanced beneath the center of the 7-9

Rewe Street property. This location is consistent with a trough in the clay surface extending from 252 Maspeth Avenue. NAPL coated and stained material was observed at borings SB-31 and SB-41 located to the west of SB-43. However, the extent of impacts under the Rewe Street properties has been delineated to the east by borings SB-44, SB-46 and SB-47 (which did not have visible impacts in this interval) and to the south by SB-39 (which did not have visible impacts in this interval) and SB-45 (which had staining and odors observed, but no NAPL saturation).

To the west of the Site and the 1 Rewe Street property, the limit of visible impacts in this interval has been delimited by SB-42 in the center of the 1 Rewe Street property and the five borings along Vandervoort Avenue (SB-1B, SB-1C, SB-6B, SB-23, SB-24 and SB-32).

A narrow and limited zone of NAPL saturation extends onto the Greenpoint Energy Center property to the north as shown by a 2 foot NAPL saturated interval from 34 to 36 ft bgs at SB-33. However, as shown on Figure 5-3, this narrow and limited zone of NAPL extends back to the Site through SB-27, but does not extend to the east, north or west at borings SB-34, SB-35, and GPEC-SB-334.

5.2.3 Lower Clay Lens

As shown on Figure 5-4, saturated NAPL impacts above the lower clay lens do not extend beyond the Site boundary, and coincide with a trough on the lower clay surface. The trough extends from beneath the northeast part of the No.1 Relief Holder to the east across all three parcels of the Site, with the lens pinching out beneath the 254 Maspeth Avenue parcel near SB-22. Depths of the NAPL ranged from 73 ft bgs (-60.19 ft NAVD88) at SB-20 to 85 ft bgs (-72.06 ft NAVD88) at SB-16C. Thicknesses of saturated NAPL lenses ranged from 0.1 ft at SB-22 to 5 ft at SB-29. NAPL saturated lenses extend from 73 to 80 ft bgs at SB-20, and a gauged DNAPL thickness of 4.8 ft was measured in the former dust suppression well PW-1, which is screened above the lower clay lens.

5.2.4 Gardiners Clay

Saturated NAPL was observed at three borings on the Gardiners Clay surface at locations beyond the limits of the lower clay or proximal to where the lower clay pinches out (Figure 5-5). These locations include SB-22 on the southern border of 254 Maspeth Avenue, SB-27 off-Site to the north at the Greenpoint Energy Center, and SB-1C southwest of former No. 1 Relief Holder along Vandervoort Avenue. NAPL was not observed to extend beyond these locations on the Gardiners Clay surface. Similar to the intermediate clay and the lower clay lens, NAPL migration follows the surface topography of the Gardiners Clay surface. Depths to saturated NAPL above the Gardiners Clay ranged from 80 ft bgs (-66 ft NAVD88) at SB-27 to 92.5 ft bgs (-79.86 ft NAVD88) at SB-22, with thicknesses of the observed saturated NAPL lenses that ranged from 0.2 ft at SB-1C to 3.5 ft at SB-22. The presence of NAPL at SB-22 is interpreted to be the result of the lower clay lens pinching out in close proximity to the boring at a location that correlates to a topographic high in the Gardiners Clay such that any NAPL perching on the lower clay lens in this area would migrate to the top of the Gardiners Clay in this area, as illustrated when comparing Figures 5-4 and 5-5.

5.3 Soil Analytical Results

During the RI activities, 56 borings and four test pits were installed and sampled. In addition, nine test pits were installed and sampled as part of the Pre-Design Investigation for Shallow Soil. A total of 171 soil samples, including nine duplicate samples, were collected and analyzed. A list of the soil samples collected and the analyses performed is provided in Table 3-1. The soil analytical results are summarized in Tables 5-3 through 5-10.

The evaluation of the soil results in the following sections is based on a comparison to the Unrestricted Use Soil Cleanup Objectives (Unrestricted Use SCOs) from 6 CRR-NY 375-6.8, Table 375-6.8(a) and the Restricted Use Soil Cleanup Objectives for Industrial Use (Industrial Use SCOs) from 6 CRR-NY 375-6.8., Table 375-6.8(b). For the constituents of interest in this RI, the Industrial Use SCO is always above the Unrestricted Use SCO. In Tables 5-3 through 5-10, where a result is above the MDL, the result is shown with a bold font; where a result is above the Unrestricted Use SCO but less than or equal to the Industrial Use SCO, the result is shaded grey; and where the result is above the Industrial Use SCO, the result is shaded yellow.

5.3.1 Surface Soils

Surface soil was sampled at four locations. The results of the surface soil samples are summarized in Tables 5-3 through 5-5. Per the RI Work Plan, four surface soil samples (and one duplicate sample) were collected from the former Site (see Figure 3-1). It should be noted that the locations where these surface soil samples were collected have since been either excavated or covered over by the property owner.

VOCs, including BTEX, were not detected in the surface soil samples (Table 5-3). Several PAHs were detected above the Unrestricted Use SCOs but below the Industrial Use SCOs in three of the samples. In sample SS-02, two PAHs were detected above the Unrestricted Use SCOs but below the Industrial Use SCOs in the primary sample, but the results from the duplicate sample were below the Unrestricted Use SCOs. Only benzo(a)pyrene was detected in three of the samples at concentrations above its Industrial Use SCO. Total PAH concentrations ranged between 6.03 mg/kg and 92.33 mg/kg in the surface soil samples. A few other SVOCs were detected at concentrations below the Unrestricted Use and Industrial Use SCOs as summarized in Table 5-4. Note that PAHs are ubiquitous in the urban environment and can be associated with run-off from asphalt pavement and atmospheric deposition.

Several metals were detected in each surface soil sample at concentrations above the Unrestricted Use SCOs but below the Industrial Use SCOs (Table 5-5). Free cyanide was not detected in any of the surface soil samples (Table 5-5).

PCB aroclors were detected in all of the surface soil samples (Table 5-5) collected from fill emplaced following cessation of MGP operations. The total PCB concentrations ranged from 0.151 mg/kg to 0.258 mg/kg and were above the Unrestricted Use SCO of 0.1 mg/kg but below the Industrial Use SCO of 25 mg/kg. Several pesticides were detected in all of the surface soil samples at concentrations above the Unrestricted Use SCOs but below the Industrial Use SCOs (Table 5-5). These included 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, dieldrin, and endrin. A couple herbicides were detected in each sample but below the Unrestricted Use SCOs. PCBs and pesticides are not associated with MGPs and are interpreted to be related to the presence of urban fill emplaced following cessation of MGP operations.

5.3.2 Subsurface Soils

The results of the subsurface soil samples are summarized in Tables 5-6 through 5-10. A total of 166 subsurface soil samples (including eight duplicate samples) were collected from the borings and test pits advanced as part of the RI and the Pre-Design Investigation for Shallow Soil. The intervals sampled and visible impacts observed at each boring and test pit location are summarized in Tables 3-1 and 5-1, respectively, and are shown on the soil boring and test pit logs in Appendices D and E, respectively.

5.3.2.1 Volatile Organic Compounds

In order to facilitate discussion of the soil VOC and SVOC sampling results, the subsurface was divided into four zones by depth: 0 to 20 ft bgs, 20 to 40 ft bgs, 40 to 60 ft bgs, and 60 ft bgs or greater. The VOC and SVOC soil results are presented on Tables 5-6 and 5-7 and Figures 5-6 through 5-9. A number of constituents in the list of analytes, including BTEX and PAHs, are commonly associated with MGP by-products, but are also found in a variety of petroleum related products associated with the other industrial/manufacturing sources that have been identified in the RI Study Area. Additionally, the list of analytes includes synthetic chemicals, e.g. chlorinated and non-chlorinated solvents that had not yet been developed or commonly used during the period of operation of the MGP. As a result, these constituents, if detected, are associated with non-MGP sources.

0 to 20 ft bgs

BTEX compounds were detected in many of the 71 subsurface soil samples collected from 0 to 20 ft bgs. Individual BTEX compounds were detected at concentrations above the Unrestricted Use SCOs in 22 of these subsurface soil samples. However, concentrations of individual BTEX compounds were detected above the Industrial Use SCOs in only two of these subsurface samples: SB-10(16-18) and SB-13(18-24). As shown on Figure 5-6, boring SB-10 was located next to the former tar tank and settling tank, and SB-13 was located under former Holder No. 1. These two samples were collected at depths coincident with NAPL saturated visible impacts (Table 5-1).

Four VOCs other than BTEX compounds were detected in subsurface soil samples collected from 0 to 20 ft bgs at concentrations above the Unrestricted Use SCOs; however, none of these detections were above the Industrial Use SCOs, as summarized in Table 5-6. Acetone was detected in a number of samples above its Unrestricted Use SCO. In sample T1-SB7(16.5-17.5), 1,2-dichlorobenzene, 1,4-dichlorobenzene and chlorobenzene were detected above the Unrestricted Use SCOs. This boring was located directly east of the former off-Site fuel oil bulk storage area, in the area of the former 10,000 gallon USTs identified on the west side of the FedEx building (Figure 3-1). This sample was collected at a depth coincident with NAPL saturated visible impacts and a naphthalene-like odor (Table 5-1).

20 to 40 ft bgs

BTEX compounds were detected in many of the 33 subsurface soil samples collected from 20 to 40 ft bgs. Individual BTEX compounds were detected at concentrations above the Unrestricted Use SCOs in 20 of these subsurface soil samples. However, concentrations of individual BTEX compounds were detected above the Industrial Use SCOs in only three of these subsurface samples: SB-3(36-38) (from boring SB-3B), SB-8(24-26) and SB-33(35-36). As shown on Figure 5-7, boring SB-3B was located at the northeast corner of the form generator building; boring SB-8 was located under former Holder No. 1, and boring SB-33 was located north of the Site on the Greenpoint Energy Center. These three samples were collected at depths coincident with NAPL saturated visible impacts (Table 5-1).

Two VOCs other than BTEX compounds were detected in subsurface soil samples collected from 20 to 40 ft bgs at concentrations above the Unrestricted Use SCOs. Acetone was detected in four samples above its Unrestricted Use SCO, and 2-butanone was detected in one sample. However, none of these detections were above the Industrial Use SCOs, as summarized in Table 5-6.

40 to 60 ft bgs

BTEX compounds were detected in many of the 28 subsurface soil samples collected from 40 to 60 ft bgs. Individual BTEX compounds were detected at concentrations above the Unrestricted Use SCOs

in nine of these subsurface soil samples. However, concentrations of individual BTEX compounds were detected above the Industrial Use SCOs in only one of these subsurface samples: SB-43(45-48). As shown on Figure 5-8, boring SB-43 is located south of the Site and just west of the former off-Site fuel oil bulk storage area. This sample was collected at a depth coincident with NAPL saturated visible impacts (Table 5-1).

No other VOCs other than BTEX compounds were detected in subsurface soil samples collected from 40 to 60 ft bgs at concentrations above the Unrestricted Use SCOs, as summarized in Table 5-6.

60 ft bgs or Greater

BTEX compounds were detected all but two of the 27 subsurface soil samples collected from 60 ft bgs or greater. Individual BTEX compounds were detected at concentrations above the Unrestricted Use SCOs in nine of these subsurface soil samples. However, concentrations of individual BTEX compounds were detected above the Industrial Use SCOs in only two of these subsurface samples: SB-27(80-85) and SB-29(98). As shown on Figure 5-9, boring SB-27 was located north of the Site on the Greenpoint Energy Center, and SB-29 was located northeast of the former settling tank at 252 Maspeth Avenue. The sample from SB-27 was collected at a depth coincident with NAPL saturated visible impacts (Table 5-1). At SB-29, no visible impacts were reported for the sampled interval, however, staining and a trace sheen was reported just above the sampled interval.

There was only one detection of a VOC other than BTEX compounds (acetone) in subsurface soil samples collected from 60 ft bgs or greater at a concentration above the Unrestricted Use SCOs, but below the Industrial Use SCOs, as shown in Table 5-6.

5.3.2.2 Semivolatile Organic Compounds

As mentioned above, the subsurface soil VOC and SVOC sampling results were divided into four zones by depth to facilitate discussion. The results are presented on Tables 5-6 and 5-7 and Figures 5-6 through 5-9.

0 to 20 ft bgs

PAH compounds were detected in all but two of the 71 subsurface soil samples collected from 0 to 20 ft bgs. Individual PAH compounds were detected at concentrations above the Industrial Use SCOs in 54 of these subsurface samples. An additional four samples had individual PAH concentrations above the Unrestricted Use SCOs but below the Industrial Use SCOs. Figure 5-6 illustrates these results.

Seven SVOCs other than PAH compounds were detected in subsurface soil samples collected from 0 to 20 ft bgs at concentrations above the Unrestricted Use SCOs, but only one of these detections was above the Industrial Use SCO (dibenzofuran), as summarized in Table 5-7. Phenolic compounds (including 2-methylphenol, 3-and 4-methylphenol, 4-methylphenol, and phenol) were detected in eight samples from seven locations at concentrations above the Unrestricted Use SCOs. All but one of these locations was located on the Site. Sample T1-SB7 (16.5-17.5) had detections of 1,2-dichlorobenzene and 1,4-dichlorobenzene above the Unrestricted Use SCOs, similar to the results discussed above for VOCs. Dibenzofuran was detected in 15 samples at concentrations above its Unrestricted Use SCO and in one sample above its Industrial Use SCO (TP-16(5-6) – this sample location has since been excavated).

20 to 40 ft bgs

PAH compounds were detected in all but four of the 33 subsurface soil samples collected from 20 to 40 ft bgs. Individual PAH compounds were detected at concentrations above the Industrial Use SCOs in 14 of these subsurface samples. One additional sample had individual PAH concentrations above the Unrestricted Use SCOs but below the Industrial Use SCOs. Figure 5-7 illustrates these results.

Four SVOCs other than PAH compounds were detected in subsurface soil samples collected from 20 to 40 ft bgs at concentrations above the Unrestricted Use SCOs; however, none of these detections were above the Industrial Use SCOs, as summarized in Table 5-7. Phenolic compounds (including 2-methylphenol, 3-and 4-methylphenol, and phenol) were detected in four samples at concentrations above the Unrestricted Use SCOs. Dibenzofuran was detected in seven samples above its Unrestricted Use SCO.

40 to 60 ft bgs

PAH compounds were detected in 17 of the 28 subsurface soil samples collected from 40 to 60 ft bgs. Individual PAH compounds were detected at concentrations above the Industrial Use SCOs in only three of these 28 subsurface samples. One additional sample had individual PAH concentrations above the Unrestricted Use SCOs but below the Industrial Use SCOs. Figure 5-8 illustrates these results.

Dibenzofuran was the only non-PAH SVOC compound detected in subsurface soil samples collected from 20 to 40 ft bgs at concentrations above the Unrestricted Use SCOs, and neither of those two detections were above the Industrial Use SCOs, as summarized in Table 5-7.

60 ft bgs or Greater

PAH compounds were detected in 16 of the 27 subsurface soil samples collected from 60 ft bgs or greater. Individual PAH compounds were detected at concentrations above the Industrial Use SCOs in only six of these 27 subsurface samples. No other samples had individual PAH concentrations above the Unrestricted Use SCOs but below the Industrial Use SCOs. Figure 5-9 illustrates these results.

No SVOCs other than PAH compounds were detected in subsurface soil samples collected from 60 ft bgs or greater at concentrations above the Unrestricted or Industrial Use SCOs.

5.3.2.3 Cyanide

Total cyanide was detected in seven of the sixteen soil samples analyzed, as summarized on Table 5-8. Detections ranged from 0.16 J mg/kg in SB-29 (0-5) to 27.5 mg/kg in TP-16 (5-6). Only the detection from TP-16(5-6) exceeded the Unrestricted Use SCO of 27 mg/kg, however, this sample location has since been excavated.

Free cyanide was detected in only three of the seventy-two samples analyzed. Detections ranged from 0.75 mg/kg in SB-8 (24-26) to 12.4 mg/kg in SB-13 (18-24).

Available cyanide was detected in eight of the seventeen samples analyzed. Detections ranged from 0.055 mg/kg in SB-19 (2-5) to 0.853 J mg/kg in TP-4 (7-7.5) (note that this sample location has since been excavated).

Part 375-6 does not include SCOs for free or available cyanide, however, the detected concentrations are below the Unrestricted Use SCO for total cyanide which is 27 mg/kg.

5.3.2.4 Metals

At least one metal was detected in all of the subsurface soil samples analyzed, as summarized in Table 5-8.

Only five metals had soil detections above the Industrial Use SCOs: arsenic, lead, manganese, mercury, and zinc. For arsenic, twenty-three samples had a concentration above the Industrial Use SCO of 16 mg/kg. These results ranged from 16.5 mg/kg at SB-12 (1-2) to 68.8 mg/kg at SB-19 (2-5). All but two of these samples were from 20 ft bgs or shallower. For lead, only two samples exceeded the Industrial Use SCO of 3,900 mg/kg: SB-12 (4-5) at 5,690 mg/kg (however, this sample was from an area that has since been excavated) and SB-45 (18-20) at 18,800 J mg/kg. For mercury, only two samples exceeded the Industrial Use SCO of 5.7 mg/kg: SB-22 (0-5) at 9.2 mg/kg (however, this sample was from an area that has since been excavated) and SB-41 (5-10) at 12.8 mg/kg. The only exceedances of the Industrial Use SCOs for manganese and zinc (both are 10,000 mg/kg) came from SB-45 (18-20) (manganese at 14,200 mg/kg and zinc at 11,400 J mg/kg).

The majority of samples had at least one metal detected above the Unrestricted Use SCOs but below the Industrial Use SCOs. These metals include barium, cadmium, chromium, copper, nickel, selenium and silver. These detections are not considered related to the operation of the former MGP and are more likely related to the presence of urban fill.

5.3.2.5 Pesticides and Herbicides

Pesticides and herbicides were detected in 10 of the 15 subsurface soil samples analyzed, as summarized in Table 5-9. None of the results exceeded the Industrial Use SCOs. None of the detections of herbicides exceeded the Unrestricted Use SCOs. The following pesticides were detected in at least one sample above the Unrestricted Use SCOs but below the Industrial Use SCOs: aldrin, 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, and dieldrin. The pesticide 4,4'-DDT was detected above its Unrestricted Use SCO in the most samples (nine samples).

5.3.2.6 Polychlorinated Biphenyls

PCB aroclors were analyzed in 45 of the subsurface soil samples (including one duplicate sample), as summarized in Table 5-9. Most of these samples were from 20 ft bgs or shallower. PCBs were detected in 15 of those samples with total PCB concentrations ranging from 0.0495 mg/kg in T2-SB4 (5-10) to 5.85 mg/kg in SB-17 (1-2). No Unrestricted Use or Industrial Use SCOs are listed for individual aroclors; however, the total PCB Unrestricted Use SCO is 0.1 mg/kg and the total PCB Industrial Use SCO is 25 mg/kg. All but two of the detections were above the Unrestricted Use SCO for total PCBs but below the Industrial Use SCO. Twelve of the 13 samples above the Unrestricted Use SCOs were from the top 6.5 ft of the surface material of the Site in fill placed following cessation of MGP operations. The remaining sample above Unrestricted use SCOs was collected at an offsite location (300 Maspeth Avenue).

The two deepest detections of PCBs in subsurface soils were noted at T1-SB7 (16.5 to 17.5 ft bgs) and T2-SB4 (5 to 10 ft bgs) collected at the 300 Maspeth Avenue property. Boring T1-SB7 was located directly east of the former off-Site fuel oil bulk storage area, in the area of the former 10,000 gallon USTs identified on the west side of the FedEx building (Figure 3-1). Boring T2-SB4 is located approximately 100 ft south of T1-SB7.

5.3.2.7 Total Petroleum Hydrocarbons

During the RI activities and the Pre-Design Investigation for Shallow Soil, 11 soil samples (including one duplicate sample) were analyzed for total petroleum hydrocarbons (TPH). In addition, 40 other samples (including two duplicate samples) were analyzed for diesel range organics (DRO) and gasoline range organics (GRO). The results are summarized on Table 5-10.

TPH detections ranged from 52.5 mg/kg [T1-SB8 (17-18.5)] to 17,500 mg/kg [T1-SB7 (22-23)]. The highest detections were from the borings directly east of the former off-Site fuel oil bulk storage area, in the area of the former 10,000 gallon USTs identified on the west side of the FedEx building. This area was given NYSDEC SPILL # 0204002 due to black stained soil with strong petroleum odor observed during underpinning work by GFE (GFE, 2002).

DRO was detected in 37 of the 40 samples at concentrations ranging from 13 mg/kg [SB-43 (49-50)] to 160,000 mg/kg [TP-16 (5-6)]. The highest detections were at TP-16 (5-6) (note that this area has since been excavated) and T5-SB2 (18-19) which is located on the east side of the FedEx building near monitoring well MW-16A. Concentrations of DRO were elevated at SB-47(10-14) advanced within the former bulk oil storage facility beneath 9 Rewe Street, consistent with the type of fuels (fuel oil) reportedly stored at that facility. Concentrations of DRO also decreased with depth at SB-47, as expected given the lighter-than-water nature of the materials (fuel oil) formerly stored in this area.

GRO was detected in 18 of the 40 samples at concentrations ranging from 1.9 mg/kg [SB-41(5-10)] to 2,500 mg/kg [SB-40 (20-23.5)]. The highest detections were at SB-40 (located to the west of the former No. 1 Relief Holder in soils coated with black viscous NAPL) and SB-43 (located to the south of the Site just west of the former off-Site fuel oil bulk storage area beneath the 9 Rewe Street building).

5.3.2.8 Summary

In the upper 20 ft of the subsurface, the horizontal extent of BTEX and PAH impacts was delineated by borings to the west along Vandervoort Ave and to the south on the 1 Rewe Street and 7-9 Rewe Street properties and the southern portion of the FedEx property, as shown on Figure 5-6. To the north, impacts were partially delineated onto National Grid's Greenpoint Energy Center which is currently being investigated under a separate RI under NYSDEC oversight. Soils east of the Site have been largely delineated with the exception of one boring T5-SB2, where there was a trace NAPL coating observed from 18.0-18.5 ft bgs within the sample interval. Samples from this boring on the east side of the FedEx building had BTEX and/or PAH results above the Industrial Use SCOs. This area is also east of the former 10,000 gallon USTs identified on the west side of the FedEx building and south of NYSDEC Spill #0202804 where 20 former USTs were excavated at the northeast corner of the FedEx building (GFE, 2002). To the north of the Site, six borings were installed on the property as shown on Figure 5-2. Delineation is complete at the western most boring on the property at SB-34 where the highest PID reading was 1.1 ppm at 18-20 ft bgs. However, to the northwest, maximum PID reading at SB-33 and SB-35 were 37.5 ppm (18-20 ft bgs) and 62.7 ppm (16-19 ft bgs), respectively. As shown in GEI borings GPEC-SB222, GPEC-SB331, GP-SB333, and GP-SB334 (Appendix D), sheens and staining with PID values above 100 ppm in the upper 20 ft are present south of the former MGP holder at the Greenpoint Site.

From 20 to 40 ft bgs (Figure 5-7), the horizontal extent of BTEX and PAH impacts is similarly delineated to the west and south. In addition, borings across Maspeth Ave provide delineation to the north, and the eastern most on-Site borings (SB-04C, SB-18 and SB-07B) provide delineation on the southeast corner of the Site.

Vertical delineation of BTEX and PAH impacts in soils is shown on Figures 5-8 and 5-9, where a small number of samples taken from 40 ft bgs or greater had BTEX and/or PAH concentrations above the Unrestricted Use SCOs and even fewer had concentrations above the Industrial Use SCOs. As shown on Figure 5-9, none of the deepest samples exceeded the Industrial Use SCOs for BTEX and/or PAHs. It is important to note that the nature and extent of environmental impacts is affected by a number of factors including historic land use and the contribution from surrounding sources. In an area with a complex history of industrial use such as the RI Study Area, it can be difficult to confirm the origin of delineated impacts, which may be the result of commingled sources in some areas.

5.4 Groundwater Analytical Results

During the RI, 38 monitoring wells were installed and sampled. A total of 42 samples, including four duplicate samples, were collected and analyzed. In addition, a sample was collected from the existing on-Site pumping well (PW-1) and groundwater grab samples were collected from two borings (GW-1 and SB-20J). A list of the groundwater samples collected and the analyses performed is included in Table 3-1. The groundwater analytical results are summarized in Tables 5-11 through 5-14. The evaluation of the groundwater results in the following sections is based on a comparison to the Ambient Water Quality Standards and Guidance Values (AWQSGVs) provided in the NYSDEC - Division of Water – Technical Operation Guidance Series (TOGS) (1.1.1) [NYSDEC, 1998, with addendums]. In Tables 5-11 through 5-14, where a result is above the MDL, the result is shown with a bold font, and where a result is above the respective AWQSGV, the result is shaded. Note that the results are compared to the AWQSGVs as per NYSDEC Guidance; however, New York City provides potable water to Brooklyn, and potential exposure related to the consumption of groundwater is not a concern.

5.4.1 Shallow Well Groundwater Samples

Twelve (12) shallow monitoring wells were installed during the RI. Except for MW-19A, these wells have 10-foot screened sections between 2.5 and 18 ft bgs, as summarized on Table 3-4. Well MW-19A has a 15-foot screen from 8 to 23 ft bgs. In addition, one groundwater grab sample was taken from a temporary well screen set from 5 to 15 ft bgs in boring SB-14B. The analyses performed for each well are summarized in Table 3-1. In total 14 shallow groundwater samples (including the groundwater grab sample and one duplicate sample) were collected and analyzed. A summary of the analytical results are tabulated in Tables 5-11 through 5-14.

5.4.1.1 Volatile Organic Compounds

Seven of the 14 shallow groundwater samples contained one or more of the BTEX compounds at concentrations above the AWQSGVs. BTEX compounds were not detected at four locations: MW-1A, MW-16A, MW-17A and MW-19A. Benzene was detected at MW-6A but not at a concentration above its AWQSGV. These wells are located along the western and southern perimeters of the Site.

Where detected, total BTEX concentrations ranged from 0.13 µg/L (MW-8A) to 15,500 µg/L (GW-1). As illustrated on Figure 5-10, the highest BTEX concentrations were detected in the vicinity of former Holder No. 1, the former Separator, and the former No. 1 and No. 2 Oil Tanks.

BTEX was also detected at concentrations above the AWQSGVs in well MW-18A which is located on the eastern border of the FedEx property line. This well is in same area as GFE well MW-7 advanced in response to NYSDEC Spill #0202804.

Other VOCs detected at concentrations above the AWQSGVs (see Table 5-11) include: acetone, isopropyl benzene, MTBE, and styrene. The groundwater grab sample, GW-1, contained MTBE (a gasoline additive in use from 1979, decades after cessation of MGP operations), isopropyl benzene, and styrene at concentrations above the AWQSGVs. These other VOCs detected indicate the contribution of off-Site sources to shallow groundwater.

5.4.1.2 Semivolatile Organic Compounds

Six of the 14 shallow groundwater samples contained one or more of the PAH compounds at concentrations above the AWQSGVs.

Where detected, total PAH concentrations ranged from 0.82 µg/L (MW-16A) to 36,627 µg/L (GW-1). As illustrated on Figure 5-10, the highest PAH concentrations were detected in the vicinity of former Holder No. 1, the former Separator, and the former No. 1 and No. 2 Oil Tanks.

Of the seventeen PAH compounds, only four PAHs (2-methylnaphthalene, acenaphthylene, benzo(g,h,i)perylene, and dibenzo(a,h)anthracene) were not detected in at least one shallow groundwater sample at concentrations above the AWQSGVs.

PAH compounds were not detected at five locations: MW-1A, MW-6A, MW-8A, MW-17A and MW-19A. At MW-2A and MW-16A, PAH compounds were detected but below the AWQSGVs. As shown on Figure 5-10, concentrations of PAHs above the AWQSGVs are limited to shallow wells on the Site and well MW-18A, located to the east of the FedEx building. In MW-18A, the only PAH concentration that exceeded its AWQSGV was naphthalene. This well is in same area as GFE well MW-7 advanced in response to NYSDEC Spill #0202804.

Several other SVOCs were detected at concentrations above the AWQSGVs in at least one sample (Table 5-12) including: 1,1'-biphenyl, 2,4-dimethylphenol, and phenol. Only samples from GW-1, MW-3A, MW-4A, MW-5A, and MW-18A had SVOCs other than PAHs detected at concentrations above the AWQSGVs.

5.4.1.3 Metals

Samples from eight of the 12 shallow monitoring wells, and the groundwater grab sample (GW-1), were analyzed for metals. Several metals were detected at concentrations above the AWQSGVs in shallow groundwater, as summarized in Table 5-13.

The metals detected at concentrations above AWQSGVs most frequently include iron, magnesium, manganese, and sodium. These metals are not related to MGP operations.

Antimony and arsenic were each detected at concentrations above AWQSGVs in three to five of the shallow groundwater samples. Antimony was above AWQSGVs in the groundwater samples collected from GW-1, MW-2A and MW-6A. Arsenic was detected at concentrations above AWQSGVs in the groundwater samples collected from GW-1, MW-3A and MW-4A.

Several metals were detected at concentrations above AWQSGVs in two or fewer shallow groundwater samples, including: beryllium, chromium, copper, nickel, selenium in GW-1; and lead, mercury, and thallium in GW-1 and MW-6A.

5.4.1.4 Total Cyanide

Samples from the twelve shallow monitoring wells, and the groundwater grab sample (GW-1), were analyzed for total cyanide, as summarized on Table 5-13.

Total cyanide was detected in 8 of the 13 shallow groundwater samples and ranged in concentration from 12.1 µg/L (GW-1) to 408 µg/L (MW-4A). Total cyanide was detected at concentrations above the AWQSGV of 200 µg/L in two of the 13 samples, those collected from MW-4A and MW-7A.

Total cyanide was not detected in the four off-Site wells located south and east of the former MGP facility (MW-16A, MW-17A, MW-18A, and MW-19A).

5.4.1.5 Polychlorinated Biphenyls

Four of the 12 shallow groundwater samples (including one duplicate sample) were analyzed for PCBs during the RI. PCBs were not detected above the reporting limit in any of the four samples analyzed (Table 5-14).

5.4.1.6 Pesticides and Herbicides

Four of the 12 shallow groundwater samples (including one duplicate sample) were analyzed for pesticides and herbicides during the RI, and the results are summarized on Table 5-14.

No pesticides were detected in the samples from MW-1A and MW-3A.

Three pesticides (beta-BHC, 4,4'-DDD and 4,4'-DDE) were detected in both the primary and duplicate samples from MW-4A. Beta-BHC and 4,4'-DDE were detected above their AWQSGVs in both samples.

Four other pesticides and two herbicides were detected in either the primary or duplicate sample from MW-4A, but none of those pesticides were detected above their AWQSGVs (if listed).

5.4.2 Intermediate Well Groundwater Samples

Sixteen (16) intermediate monitoring wells were installed during the RI. These wells have 10-foot screened sections between 25.5 and 48 ft bgs, as summarized on Table 3-4. The analyses performed for each well are summarized in Table 3-1. A total of 15 intermediate well groundwater samples (including two duplicate samples) were collected and analyzed. A summary of the analytical results are tabulated in Tables 5-11 through 5-14.

5.4.2.1 Volatile Organic Compounds

Twelve (12) of the 15 intermediate groundwater samples contained one or more of the BTEX compounds at concentrations above the AWQSGVs.

Where detected, total BTEX concentrations ranged from 15 µg/L (MW-6B) to 33,200 µg/L (MW-5B). As illustrated on Figure 5-11, the highest BTEX concentrations in the intermediate groundwater zone were detected in the vicinity of the former separator and west of the former No. 1 and No. 2 Oil Tanks, and at MW-19B south of and downgradient of the Site along Rewe Street.

BTEX constituents were detected at concentrations above the AWQSGVs in well MW-5B located adjacent to the former MGP operations area and MW-19B located south of the former MGP on Rewe Street (Figure 4-15). There were no observed impacts in screened zone at MW-19B. This well is also located downgradient of the former oil storage facility located beneath the 7-9 Rewe Street property. Petroleum stained shallow soils were observed just east of this area by GFE in 2002-2003 while performing underpinning work at the FedEx facility located at 300 Maspeth Avenue.

At MW-16B (east of the Site along the FedEx property line), only benzene was detected above its AWQSGV. Well MW-16B is screened at the top of the intermediate clay, and there were no observations of impacts noted in soils within the screened interval.

BTEX constituents were not detected at two locations: MW-17B and MW-18B, which are located off-Site to the south and west. No other VOCs were detected at these two locations at concentrations above the AWQSGVs.

BTEX is more prevalent and present at higher concentrations in the intermediate zone groundwater than in the shallow zone groundwater beneath the RI Study Area, consistent with the observation of visible subsurface impacts and locations where soil detections were above Industrial Use SCOs. The exception is at the MW-18A/B/C well cluster, where shallow groundwater had concentrations of BTEX compounds above the AWQSGVs but the intermediate groundwater did not have any detections of BTEX compounds. As stated previously, this well is in same area as GFE well MW-7 advanced in response to NYSDEC Spill #0202804.

Other VOCs detected at concentrations above the AWQSGVs (see Table 5-11) include: acetone, isopropyl benzene, styrene, and chlorinated VOCs. Chlorinated VOCs were detected at concentrations above the AWQSGVs in groundwater samples collected from wells MW-1B, MW-2B, MW-7B, MW-8B, and MW-19B. The first four wells listed are located on the Site, and MW-19B is off-Site to the south along Rewe Street. The highest tetrachloroethene (PCE) and trichloroethene (TCE) concentrations were found in well MW-1B, which is located cross-gradient / upgradient of the Site (Figures 4-14 and 4-15). Chlorinated VOCs are not associated with former MGP operations.

5.4.2.2 Semivolatile Organic Compounds

Seven of the 15 intermediate groundwater samples contained one or more of the PAH compounds at concentrations above the AWQSGVs.

Where detected, total PAH concentrations ranged from 3.0 µg/L (MW-1B) to 10,056 µg/L (MW-5B). As illustrated on Figure 5-11, the highest PAH concentrations were detected in the vicinity of the former separator and the former No. 1 and No. 2 Oil Tanks.

Ten (10) of the 17 PAH compounds were detected in at least one intermediate groundwater sample at concentrations above the AWQSGVs: acenaphthene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, fluorene, indeno(1,2,3-cd)pyrene, naphthalene, and phenanthrene.

PAH compounds were not detected at four locations: MW-6B, MW-11B, MW-12B, and MW-17B. At MW-1B and MW-16B, PAH compounds were detected but below the AWQSGVs.

As shown on Figure 5-11, concentrations of PAHs above the AWQSGVs are limited to intermediate wells on the Site and off-Site wells MW-18B (located to the east of the FedEx building) and MW-19B

(located to the south along Rewe Street). At MW-18B, the only PAH concentration that exceeded its AWQSGV was naphthalene (similar to the results for the shallow groundwater well at this location). The naphthalene concentration decreased with depth at this location. At MW-19B, the only PAH concentrations that exceeded their AWQSGVs were for acenaphthene and naphthalene. PAH concentrations at this location increased with depth (PAHs were non-detect in MW-19A).

PAHs are more prevalent and present at higher concentrations in the intermediate zone groundwater than in the shallow zone groundwater beneath the RI Study Area, consistent with the observation of visible subsurface impacts and locations where soil detections were above Industrial Use SCOs. The exception is at the MW-18A/B/C well cluster, where the total PAH concentration decreased from 103.88 µg/L in the shallow groundwater to 27.53 µg/L in the intermediate groundwater. This well cluster is in same area as GFE well MW-7. This well was installed within the former excavation performed to remove twenty 550-gallon USTs and the 2 gallons of diesel released in 2002. This work was performed under NYSDEC Spill #0202804 (GFE, 2002).

Several other SVOCs were detected at concentrations above the AWQSGVs in at least one sample (Table 5-12) including: 1,1'-biphenyl, 2,4-dimethylphenol, bis(2-Ethylhexyl) phthalate, and phenol. Only samples from MW-2B, MW-4B, MW-5B, MW-7B, MW-11B, MW-17B, MW-18B and MW-19B had SVOCs other than PAHs detected at concentrations above the AWQSGVs.

5.4.2.3 Metals

A total of 10 intermediate well samples (including one duplicate sample) were analyzed for metals, and the results are summarized in Table 5-13.

Several metals were detected at concentrations above the AWQSGVs in intermediate groundwater. The metals detected at concentrations above AWQSGVs most frequently include iron, magnesium, and sodium. These metals are not related to MGP operations.

Arsenic, barium, copper and manganese were each detected at concentrations above AWQSGVs in two or fewer intermediate groundwater samples. Arsenic and copper were above AWQSGVs in the groundwater sample collected from MW-4B. Barium was above its AWQSGV in the groundwater sample collected from MW-11B. Manganese was above its AWQSGV in the groundwater samples collected from MW-1B and MW-7B.

5.4.2.4 Total Cyanide

All 15 samples from the intermediate monitoring wells (including two duplicate samples) were analyzed for total cyanide, as summarized on Table 5-13.

Total cyanide was detected in 11 of the 15 intermediate groundwater samples and ranged in concentration from 11.4 µg/L (MW-2B) to 202 µg/L (MW-5B). Total cyanide was detected at a concentration slightly above the AWQSGV of 200 µg/L in only one sample: MW-5B at 202 µg/L.

5.4.2.5 Polychlorinated Biphenyls

One of the 15 intermediate groundwater samples (MW-1B) was analyzed for PCBs during the RI. PCBs were not detected above the reporting limit in this sample (Table 5-14).

5.4.2.6 Pesticides and Herbicides

One of the 15 intermediate groundwater samples (MW-1B) was analyzed for pesticides and herbicides during the RI. Pesticides and herbicides were not detected above the reporting limit in this sample (Table 5-14).

5.4.3 Deep Well Groundwater Samples

Twelve (12) deep monitoring wells were installed during the RI and generally screened above the top of the Gardiners Clay. These wells have 10-ft screened sections between 67 and 110 ft bgs, as summarized on Table 3-4. In addition the existing on-Site pumping well has a 15-foot screen from 63 to 78 ft bgs. The analyses performed for each sample are summarized in Table 3-1. A total of 14 deep well groundwater samples (including one duplicate sample) were collected and analyzed. A summary of the analytical results are tabulated in Tables 5-11 through 5-14.

5.4.3.1 Volatile Organic Compounds

Ten (10) of the 14 deep groundwater samples contained one or more of the BTEX compounds at concentrations above the AWQSGVs.

Where detected, total BTEX concentrations ranged from 0.26 µg/L (MW-10C) to 14,870 µg/L (MW-3C). As illustrated on Figure 5-12, the highest BTEX concentrations in the deep groundwater zone were detected on-Site near the on-Site pumping well (PW-1 and MW-8C) and east of this area at MW-3C.

An elevated total BTEX concentration (2,973 µg/L) was also reported for off-Site well MW-16C, located downgradient of the Site to the east of the FedEx building. Well MW-16C screened above the Gardiners Clay, at a low spot in the top of the clay surface. The total BTEX concentration was two orders of magnitude lower in the intermediate groundwater at this well cluster (15.7 µg/L) and non-detect in the shallow groundwater.

At downgradient well MW-19C, only benzene was detected above its AWQSGV and the total BTEX concentration (16.88 µg/L) was two orders magnitude lower than in intermediate groundwater at this location (9,445 µg/L). BTEX compounds were not detected in the shallow groundwater at this location.

BTEX constituents were not detected at two locations: MW-17C and MW-18C (similar to the intermediate zone), which are located off-Site to the south and west. At MW-18C, two chlorinated VOCs were detected at concentrations above the AWQSGVs; however, at MW-17C no other VOCs were detected at concentrations above the AWQSGVs. Chlorinated VOCs are not associated with former MGP operations.

BTEX in the deep zone groundwater is consistent with the observation of visible subsurface impacts and locations where soil detections were above Industrial Use SCOs. The exceptions are at the MW-4 and MW-18 well clusters, where shallow groundwater had the highest total BTEX concentrations, and at the MW-19 well cluster where the intermediate groundwater had the highest total BTEX concentration.

Other VOCs detected at concentrations above the AWQSGVs (see Table 5-11) include: isopropyl benzene, styrene, and chlorinated VOCs. Chlorinated VOCs were detected at concentrations above the AWQSGVs in groundwater samples collected from all the deep wells except well MW-17C (located off-Site southeast of the Site along Rewe Street). At wells MW-9C, MW-10C, and MW-18C,

the only VOCs with concentrations above the AWQSGVs were chlorinated VOCs. Wells MW-9C and MW-10C are located to the west of the Site along Vandervoort Ave. Well MW-18C is located off-Site east of the FedEx building. Chlorinated VOCs are not associated with former MGP operations.

5.4.3.2 Semivolatile Organic Compounds

Eight of the 14 deep groundwater samples contained one or more of the PAH compounds at concentrations above the AWQSGVs.

Where detected, total PAH concentrations ranged from 3.0 µg/L (MW-17C) to 3,883 µg/L (PW-1). As illustrated on Figure 5-12, the highest PAH concentrations in the deep groundwater zone were detected on-Site at or near the former on-Site pumping well (PW-1 and MW-8C), at MW-3C and near the former No. 1 and No. 2 Oil Tanks.

An elevated total PAH concentration (1,207.8 µg/L) was also reported for off-Site well MW-16C, located to the east of the FedEx building. The total PAH concentration increased with depth at this location (MW-16B - 9.4 µg/L and MW-16A - 0.82 µg/L). This pattern is similar to that observed for BTEX at this well cluster.

PAH compounds were not detected at three locations: MW-9C, MW-10C and MW-18C. Wells MW-9C and MW-10C are located upgradient and to the west of the Site along Vandervoort Ave. Well MW-18C is located off-Site to the east of the FedEx building. No other SVOCs were detected at concentrations above the AWQSGVs at these locations.

PAHs in deep zone groundwater are consistent with the observation of visible subsurface impacts and locations where soil detections were above Industrial Use SCOs. The exceptions are at the MW-4 and MW-18 well clusters, where shallow groundwater had the highest total PAH concentrations, and at the MW-19 well cluster where the intermediate groundwater had the highest total PAH concentration.

Several other SVOCs were detected at concentrations above the AWQSGVs in at least one sample (Table 5-12) including: 1,1'-biphenyl, bis(2-Ethylhexyl) phthalate, and phenol. Only six samples (from PW-1, MW-1C, MW-3C, MW-4C, MW-8C, and MW-11C) had SVOCs other than PAHs detected at concentrations above the AWQSGVs.

5.4.3.3 Metals

Ten deep well samples (including one duplicate sample) were analyzed for metals, and the results are summarized in Table 5-13.

Several metals were detected at concentrations above the AWQSGVs in deep groundwater, including iron, magnesium, manganese, and sodium. These metals are not related to MGP operations. No other metals were detected at concentrations above AWQSGVs in the deep groundwater samples.

5.4.3.4 Total Cyanide

All 14 samples from the deep monitoring wells (including one duplicate sample) were analyzed for total cyanide, as summarized on Table 5-13.

Total cyanide was detected in nine of the 14 deep groundwater samples and ranged in concentration from 6.0 J µg/L (MW-9C) to 100 µg/L (MW-18C). Total cyanide was not detected in any of the deep groundwater samples at a concentration above the AWQSGV of 200 µg/L.

5.4.3.5 Polychlorinated Biphenyls

Two of the 14 deep groundwater samples (MW-1C and MW-3C) were analyzed for PCBs during the RI. PCBs were not detected above the reporting limit in these samples (Table 5-14).

5.4.3.6 Pesticides and Herbicides

Two of the 14 deep groundwater samples (MW-1C and MW-3C) were analyzed for pesticides and herbicides during the RI. Pesticides and herbicides were not detected above the reporting limit in these samples (Table 5-14).

5.4.3.7 Summary

Dissolved phase impacts in shallow zone (water table) wells are largely isolated to the former Site boundary, with significantly lower levels (typically low to non-detect) at upgradient wells along Vandervoort Avenue and at downgradient and crossgradient wells along Rewe Street and at FedEx. The highest levels of dissolved BTEX and PAHs in water table wells were noted at GW-1 adjacent to former No. 1 Relief Holder and at MW-4A adjacent to the former No. 1 and No. 2 Oil Tanks (Figure 5-10).

Dissolved phase impacts in the intermediate portion of the overburden aquifer are generally the highest observed in the RI Study Area, consistent with this zone containing the most widespread presence of NAPL. Dissolved BTEX and PAHs were highest at on-Site wells MW-5B and MW-7B and decreasing in the direction of groundwater flow towards MW-19B along Rewe Street (Figure 5-11). Low (< 100 µg/L) to non-detectable levels of BTEX and PAHs were noted at upgradient wells along Vandervoort Avenue and at downgradient and cross-gradient wells to the east of the Site at FedEx. Given the trends observed in the data, it is likely that dissolved phase concentrations of these constituents will decrease further at locations outside of the RI Study Area due to biodegradation, attenuation, and dilution.

Dissolved phase impacts in the deepest portion of the overburden aquifer above the Gardiners Clay are generally consistent with the overlying intermediate zone. Dissolved BTEX and PAHs were highest at MW-3C and MW-8C within the Site boundary and decreasing in the direction of groundwater flow towards MW-16C along the eastern side of the 300 Maspeth Avenue property (Figure 5-12). Low (< 100 µg/L) to non-detectable levels of BTEX and PAHs were noted at upgradient wells along Vandervoort Avenue and at downgradient and cross-gradient wells MW-17C and MW-18C to the east of the Site at FedEx.

The dissolved-phase impacts are the result of a number of factors including geologic conditions, groundwater flow patterns and the presence of source material in soil. As indicated previously, source material in the RI Study Area may originate from a number of sources with similar characteristics. As a result, the dissolved phase impacts may be associated with commingled sources. The potential for commingled impacts is supported by the presence of constituents, such as chlorinated solvents, which were not in use during the period of operation of the MGP.

5.5 Non-Aqueous Phase Liquid Baildown Testing Results

On March 12, 2010, DNAPL baildown tests were successfully initiated at wells PW-1 and MW-3B (Figure 3-1), which had initial DNAPL thicknesses and volumes of 2.61 ft / 6 gallons and 5.18 ft / 3 gallons, respectively. During purging slightly more than the total effective well volume (volume within the well casing plus pore space in the sand pack) was removed from each well. Following the removal

of DNAPL thicknesses from these wells, the wells were gauged periodically to assess the rate of DNAPL recovery in each well. The DNAPL in MW-3B recovered to its initial thickness after approximately 5 days. DNAPL in well PW-1 had not recovered a measurable amount of DNAPL thickness as of April 2nd, 2010 (21 days after removing the DNAPL).

Based on the recovery data, DNAPL around well MW-3B was considered recoverable while the data at PW-1 indicated a significantly lower potential for recoverability given the lack of DNAPL recovery observed at this well over time.

In February 2012, DNAPL baildown recovery tests were performed at wells MW-14B and MW-15B. MW-14B showed a low potential for recoverability and well MW-15B showed a relatively high potential for recoverability based on the testing results.

DNAPL fluid property results are presented in Table 5-15. In summary, the results for viscosity, density, and interfacial tension showed differences in density and viscosity that are likely the result of different DNAPL sources or variability in weathering of the DNAPL over time.

5.6 Vapor Intrusion Evaluation Sample Results

Vapor intrusion sampling was conducted at four properties on/adjacent to the Site over five events in 2009, 2010 (two events), 2011, and 2015. Four rounds of samples were collected from 222 Maspeth Ave, two rounds were collected from 252 Maspeth Ave, and one round was collected from both 1 Rewe Street and 7-9 Rewe Street. At each location a pair of sub-slab vapor and indoor air samples was collected, along with one outdoor ambient air sample per event.

A list of the sub-slab vapor, indoor air, and ambient air samples collected, and the analyses performed, is included in Table 3-2. The results of the sub-slab vapor and indoor air evaluation samples are summarized in Table 5-16 and illustrated on Figure 5-13.

The results were compared to typical indoor air concentrations (also referred to as “background concentrations”) identified based on the USEPA study of randomly selected public and commercial office buildings, and published in NYSDOH’s Vapor Intrusion Guidance Document (2006). The NYSDOH background concentrations are listed on Table 5-16.

5.6.1 222 Maspeth Avenue

At 222 Maspeth Ave, four rounds of vapor intrusion evaluation sampling were conducted. The samples were collected from the ground floor (locker room area) of the office structure.

5.6.1.1 November 2009 Event

The initial round sampling was conducted in November 2009 as part of the RI activities.

In the sub-slab vapor sample, a number of compounds were detected above their NYSDOH background levels. Most of these were also detected in the indoor air sample above the NYSDOH background concentrations, including ethylbenzene, naphthalene, styrene, toluene, and xylenes.

Methylene chloride was also detected in the indoor air sample at a concentration above the NYSDOH background level. However, this compound was detected at a lower concentration in the sub-slab vapor sample.

However, a number of products were identified in the locker room in the pre-sampling survey which may have interfered with the sampling (e.g., lubricants, stains, adhesives, paints, and varnish removers /strippers).

5.6.1.2 March 2010 Event

As a result of the detections found in the November 2009 sampling event, it was determined that a second round of sampling would be conducted in March 2010 during the heating season to verify the results. (NYSDOH Vapor Intrusion Guidance considers the heating season to be between November 15 and March 31.) Prior to the March 2010 sampling, the locker room was cleared of various products which may have interfered with the sampling (e.g., lubricants, stains, adhesives, paints, and varnish removers /strippers).

Although the March 2010 sampling still revealed the presence of ethylbenzene, styrene, toluene, xylenes, and methylene chloride in indoor air, they were detected below NYSDOH background concentrations.

Naphthalene was detected in the indoor air sample from the locker room above background concentrations in both the November 2009 and March 2010 sampling events. It was also detected in the sub-slab vapor samples during these events at concentrations higher than the indoor air sample. Based on the sampling results, it was concluded that the naphthalene may be migrating into the locker room from below the floor slab.

5.6.1.3 August 2010 Event

After completion of the March 2010 sampling event, National Grid was informed, for the first time, of potential pathways for sub-slab vapor migration into the locker room, including a previously unknown gap around a sewer cleanout in the locker room floor and unknown smaller gaps and cracks in the floor of the water meter pit and around conduits entering the water meter pit from the subsurface. In light of this new information, the potential pathways observed in the locker room floor were sealed with cement/concrete and/or non-VOC caulk, and an additional sampling event was planned.

In August 2010, a third round of sampling was conducted in the locker room to verify the effectiveness of the remedial actions taken to seal the identified migration pathways. Prior to the sampling event, screening was completed in the locker room to remove all materials that might interfere with indoor air sampling. However, the lockers were locked and the absence of indoor air sources could not be verified. Therefore, screening was completed through the vents of the lockers using a photoionization detector (PID); the PID readings were not elevated.

In the August 2010 sampling, ethylbenzene, styrene, toluene, xylenes, 2-butanone, carbon tetrachloride, ethanol, TCE, 1,2,4- and 1,3,5-trimethylbenzene and 4-ethyltoluene were detected in the indoor air sample above NYSDOH background concentrations. However, these constituents were detected at lower concentrations in the sub-slab vapor sample than in the indoor air sample. Ethylbenzene, styrene, toluene, and xylenes are ingredients in gasoline, spray paint, adhesives, degreasers, etc. 2-Butanone, also known as methyl ethyl ketone (MEK), can be found in paints, glues, other finishes, and also exhaust from cars and trucks. Carbon tetrachloride is used as a solvent, petrol additive, and as an ingredient in refrigerants, and metal degreasing. Ethanol is an ingredient in spray paint, glass cleaner, lubricants, adhesives, laundry detergents, fabric softeners, etc. Ethanol is also used in combustion engines as fuel. TCE is a solvent for degreasing metal parts and an ingredient in products such as adhesives and paint removers.

Chloroform was detected in indoor air and sub-slab vapor during the August 2010 sampling event. The indoor air concentration was slightly above the background concentration. Chloroform and was not detected in indoor air during the two previous sampling events. Chloroform can be found in products including adhesive removers, glass cleaners, and air fresheners.

Carbon disulfide, PCE, and trichlorofluoromethane were detected in the sub-slab vapor sample above their NYSDOH background levels; however, they were detected at concentrations below their background levels in the paired indoor air sample.

The results of the August 2010 sampling event showed that naphthalene concentrations detected in indoor air prior to the mitigation effort decreased to below background concentrations, indicating that the mitigation of potential pathways (i.e., sealing openings to the subsurface within the building) was successful at reducing the potential migration of naphthalene into the locker room from beneath the floor slab. To confirm this, a fourth sampling event was planned for the 2010-2011 heating season.

5.6.1.4 February 2011 Event

Finally, a fourth round of sampling in the locker room was conducted in February 2011 (in the heating season) to confirm the August 2010 results.

Prior to the February 2011 sampling event, screening was completed in the locker room to identify any materials that might interfere with indoor air sampling. Although no potential indoor air sources were observed in the locker room, the lockers were locked and thus the absence of indoor air sources could not be verified. Screening was also completed through the vents of the lockers using a PID, and the PID readings were not elevated.

The February 2011 sampling revealed the presence of toluene, ethanol, and methylene chloride in the indoor air above NYSDOH background concentrations. However, these constituents were detected at lower concentrations in the sub-slab vapor sample than in the indoor air sample. Toluene is an ingredient in gasoline, spray paint, adhesives, degreasers, etc. Ethanol is an ingredient in spray paint, glass cleaner, lubricants, adhesives, laundry detergents, fabric softeners, etc. Ethanol is also used in combustion engines as fuel. Methylene chloride is an ingredient in auto maintenance products including lubricants, degreasers, gasket remover, valve, brake parts, and tire cleaner; home maintenance products including spray paint, stain strippers, varnish and adhesive remover; and in pesticides.

The February 2011 sampling also revealed the presence of chloroform in the indoor air at a concentration approximately equal to the NYSDOH background concentration. It was also detected in sub-slab vapor at a higher concentration than in indoor air. Chloroform was detected in indoor air and sub-slab vapor during the previous sampling event conducted in August 2010, but was not detected in indoor air in the two sampling events conducted prior to August 2010. Chloroform can be found in products including adhesive removers, glass cleaners, and air fresheners. During prior sampling events at this property, many of these items (paint, adhesives, degreasers) were present in various areas.

Dichlorodifluoromethane, PCE, and trichlorofluoromethane were detected in the sub-slab vapor sample above their NYSDOH background levels; however, they were either not detected or detected at concentrations below their background levels in the paired indoor air sample.

The results of the February 2011 sampling event show that naphthalene concentrations detected in indoor air prior to the July 2010 mitigation effort have decreased to below the background concentration, confirming that the mitigation of potential pathways (i.e., sealing openings to the subsurface within the building) was successful.

5.6.2 252 Maspeth Avenue

At 252 Maspeth Ave, two rounds of vapor intrusion evaluation sampling were conducted. The samples were collected from the ground floor of the mechanics shop.

5.6.2.1 November 2009 Event

The initial round sampling was conducted in November 2009 as part of the RI activities.

In the sub-slab vapor sample, a number of compounds were detected above their NYSDOH background levels; however, in the paired indoor air sample, these compounds were either not detected or detected at a concentration below their NYSDOH background level. In particular, PCE and TCE were detected at concentrations exceeding DOH action levels for these compounds in air. PCE and TCE are associated with de-greasers and solvents. Neither PCE nor TCE were detected in the indoor air sample.

Only hexane and ethanol were detected in the indoor air sample at concentrations above their NYSDOH background levels.

Hexane was detected in indoor air at a concentration slightly above the NYSDOH background level. Hexane, however, was not detected in the sub-slab vapor sample, therefore, the detected hexane is interpreted to be from an indoor source. Hexane is an ingredient in products including gasoline, spray paint, adhesives, brush cleaners, lubricants, and liquid electrical tapes. An inventory of products in the garage conducted prior to sampling revealed the presence of lacquer thinner, which may have been the source of the hexane detected in indoor air.

Ethanol was detected in indoor air at a concentration above the background concentration; however, it was not detected in the sub-slab vapor sample. Ethanol is an ingredient in spray paint, glass cleaner, lubricants, adhesives, laundry detergents, fabric softeners, etc. Ethanol is also used in combustion engines as fuel.

There were detections of various constituents in the ambient air samples during the sampling event, consistent with typical urban background concentrations.

5.6.2.2 March 2010 Event

After the November 2009 results were evaluated, it was determined that the indoor air sample was collected during business hours on a week day while work was being conducted in the garage with one of the garage doors open. To ensure that results of the vapor intrusion evaluation were as accurate as possible, an additional round of sampling was conducted in March 2010, during the heating season, with all garage doors closed. Prior to the March 2010 sampling, the garage was cleared of all products which might interfere with the sampling (i.e., cleaners, paints, solvents, petroleum products, etc.).

As in November 2009, a number of compounds, including PCE and TCE, were detected in the sub-slab vapor sample above their NYSDOH background levels. However, in the paired indoor air sample,

these compounds were either not detected or detected at a concentration below their NYSDOH background level.

No compounds were detected in the indoor air sample at a concentration above the NYSDOH background levels. Hexane and ethanol were detected but not above background. The lower indoor air results reported for the March 2010 event suggests that the November 2009 results may have been affected by the thinner and other products removed from the garage prior to the March sampling event, as well as the work that was going on during the November sampling.

5.6.3 1 Rewe Street

The RI Work Plan Addendum No. 4 (AECOM, 2015) included vapor intrusion sampling at the private property located to the south of the Site at 1 Rewe Street. At this location, one set of paired indoor air / sub-slab vapor samples was collected from the north end of the building and one pair from the south end.

In the north end of the building in the sub-slab vapor sample, a number of compounds were detected above their NYSDOH background levels. However, with the exception of styrene (as discussed below), these compounds were either not detected in the paired indoor air sample or detected at a concentration below their NYSDOH background level.

In the south end of the building, only styrene was detected in both the sub-slab vapor and indoor air at concentrations above the NYSDOH background level.

However, the styrene concentrations in the indoor air samples from the north and south ends of the building were greater than in the paired sub-slab vapor samples. If the vapor intrusion pathway were the source of the styrene, it would be expected to be present in the sub-slab vapor samples at concentrations greater than in the indoor air samples. Styrene is used in many applications including containers, protective packaging, and electronics, which were observed within the building during the pre-sampling survey.

5.6.4 7-9 Rewe Street

The RI Work Plan Addendum No. 4 (AECOM, 2015) included vapor intrusion sampling at the private property located to the south of the Site at 7-9 Rewe Street. At this location, one set of samples was collected from the north end of the building.

Three compounds were detected in the sub-slab vapor sample at concentrations above their NYSDOH background level: hexane, styrene, 1,3-butadiene, and PCE. 1,3-butadiene was not detected in the paired indoor air sample.

Hexane, styrene, and PCE were also detected in the indoor air sample at concentrations above the NYSDOH background levels. However, the indoor air concentrations were higher than in the sub-slab vapor sample. If the vapor intrusion pathway were the source of these compounds, it is expected that concentrations of these compounds would be present in the sub-slab vapor sample at concentrations greater than those in the indoor air sample.

Hexane is an ingredient in products including gasoline, spray paint, adhesives, brush cleaners, lubricants, and liquid electrical tapes. Styrene is used in many applications including containers, protective packaging, and electronics. PCE is associated with de-greasers and solvents. The pre-

sampling product inventory revealed the presence of multiple products, including adhesive spray, cleaners, diesel fluids, transmission fluids, motor/engine oils, and protective enamels which may be a source of volatile compounds in indoor air.

6.0 Summary of Interim Remedial Measures

6.1 Vapor Intrusion Mitigation – Locker Room (222 Maspeth Avenue)

As discussed in Section 5.6, vapor intrusion samples (a pair of sub-slab vapor and indoor air samples and one outdoor ambient air sample) were collected from the ground floor locker room area of the office structure at 222 Maspeth Ave in November 2009 as part of the initial RI activities. The results were compared to typical indoor air concentrations (also referred to as "background concentrations") identified based on the USEPA study of randomly selected public and commercial office buildings, and published in NYSDOH's Vapor Intrusion Guidance Document (2006). The vapor intrusion sampling results are summarized in Table 5-16.

The November 2009 results showed a number of compounds detected in the indoor air sample above the NYSDOH background concentrations, including ethylbenzene, naphthalene, styrene, toluene, and xylenes. However, a number of products were identified in the locker room in the pre-sampling survey which may have interfered with the sampling (e.g., lubricants, stains, adhesives, paints, and varnish removers /strippers), therefore, a second round of sampling was conducted in March 2010.

Prior to the March 2010 sampling, the locker room was cleared of various products which may have interfered with the sampling (e.g., lubricants, stains, adhesives, paints, and varnish removers /strippers). Naphthalene was detected in the indoor air sample from the locker room above background concentrations, and as a result, it was concluded that the naphthalene may be migrating into the locker room from below the floor slab.

After completion of the March 2010 sampling event, potential pathways for sub-slab vapor migration into the locker room, including a gap around a sewer cleanout in the locker room floor and unknown smaller gaps and cracks in the floor of the water meter pit and around conduits entering the water meter pit from the subsurface were sealed with cement/concrete and/or non-VOC caulk. Appendix M contains pictures of the remediated areas. A third and fourth round of vapor intrusion sampling was conducted in August 2010 and February 2011 to verify the effectiveness of the remedial actions taken to seal the identified migration pathways.

The results of both sampling events showed that naphthalene concentrations detected in indoor air prior to the mitigation effort decreased to below background concentrations, indicating that the mitigation of potential pathways (i.e., sealing openings to the subsurface within the building) was successful at reducing the potential migration of naphthalene into the locker room from beneath the floor slab.

6.2 Interim Site Management Plan

In accordance with the requirements of DER-10 (NYSDEC, 2010), an Interim Site Management Plan (ISMP) (AECOM, 2012) was prepared on behalf of the National Grid to alert Site workers and construction, utility and maintenance crews, and their contractors ("Construction Workers") that there are environmental conditions on the 222 Maspeth Avenue, 252 Maspeth Avenue, and 254 Maspeth Avenue properties in Brooklyn, New York that may impact surface intrusive (i.e., greater than 6 inches deep, such as drilling, excavation, utility repairs, fence repairs, tree planting, construction, etc.)

activities and present a hazard to the public and environment. Work within the above properties has the potential for contact with environmental impacts during surface intrusive activities. The ISMP is currently being modified to include protective measures for the NAPL recovery system treatment trailer installed in the southwest corner of the 254 Maspeth Avenue parcel. The NAPL recovery system is comprised of 23 recovery wells and an associated control trailer housing pump controls and a 500-gallon NAPL recovery tank that are located in the southwest corner of the 254 Maspeth Avenue parcel. The control trailer is surrounded by a jersey barrier and locked fencing to isolate truck traffic and limit unauthorized access.

The primary goal of the ISMP is to ensure that any surface intrusive work will be done in such a manner that Construction Worker and general public (including Site worker) will be prevented from exposure to environmentally impacted material at the Site through work zone controls, appropriate monitoring, and safe work practices. A secondary goal of the ISMP is to ensure unauthorized access to the NAPL recovery system is prevented.

The ISMP requires the Site owner(s) or their representative(s) to notify National Grid and NYSDEC at least 15 business days prior to the start of:

- Any intrusive activity that is anticipated to penetrate the Site surface, disturb the Site surface, or encounter the Site subsurface.
- Any contaminated soil handling activities, intrusive or non-intrusive.
- Any subsurface modifications or repairs to the existing stormwater collection system and other subsurface equipment (including scales), and utilities or future Site development/redevelopment.
- Any work that will require access to the NAPL recovery treatment system control trailer or fenced area or recovery well vaults.

National Grid will review and provide comments on all planned surface-intrusive activities, and may opt to have a representative on-site, as appropriate, to observe that any surface-intrusive work activities are done in compliance with the ISMP.

The ISMP requires that all surface intrusive work be performed in compliance with 29 CFR 1910.120 and utilize appropriate Occupational Safety and Health Administration (OSHA) Hazardous Waste Operations and Emergency Responses (HAZWOPER) trained workers. Such work must also be conducted under a Health and Safety Plan (HASP) and a Community Air Monitoring Plan (CAMP). The ISMP also requires that certain engineering controls be used to protect public safety during such work. The ISMP also details specific measures to be taken for on-site material management, waste management, stormwater pollution prevention, and equipment decontamination.

The ISMP also states that entry to the NAPL recovery system control trailer or the recovery well vaults is not permitted, unless accompanied by National Grid or their representatives.

6.2.1 Cooper Tank Wall Foundation Work (252 and 254 Maspeth Avenue)

On November 28, 2012, GFE on behalf of Cooper Tank notified NYSDEC and National Grid of planned construction activities at the 254 Maspeth Ave property, as required by the ISMP. The surface intrusive work was conducted on December 17 through 27, 2012 and involved construction of a foundation for a perimeter wall around the property that would involve excavation of Site soils.

AECOM provided oversight for National Grid, performed the required Community Air Monitoring and ensured that soils were managed properly for disposal.

The work included:

- Excavation and stockpiling of Interim Remedial Measure (IRM) stone backfill for Site reuse;
- Excavation and disposal of wall footing soil not approved for reuse on-site; and
- Excavation and disposal of wall footing soils with environmental impacts based on field/visual observations.

Figure 6-1 shows the limits of the work. The wall excavation activities included the installation of a demarcation layer within the footprint of the proposed wall construction activities at the Site. This activity was performed to allow the Site wall foundation contractor (DCMI) access to the area without properly trained (40 hour HAZWOPER) staff to handle environmental impacts. EQ Northeast was selected by Cooper Tank to serve as the contractor to excavate the wall footprint and lay in the demarcation layer along the bottom and sidewalls of the wall trench. AECOM served as the Site engineer and provided the day to day oversight of the contractor and managed the Community Air Monitoring Program.

EQ Northeast removed 150 cubic yards of stone backfill from Area D (shown on Figure 6-1) identified during the shallow soil IRM activities performed in September 2012 (as summarized in Section 6.3). All stone was stockpiled in the Southwest part of the Site for future use. EQ Northeast initially planned to reuse 450 cubic yards of soil from the wall foundation footprint throughout the Site since environmental impacts were not present based on visual/field screening operations. However, during the wall excavation EQ Northeast identified the soil as unusable for Site reuse due to the presence of large amounts of non-soil debris mixed throughout (i.e. bricks, carpet, wood, rocks, and concrete chunks). The soils within the wall foundation areas were pre-characterized for off-site thermal treatment at Bayshore Soil Management LLC.

The work was conducted in accordance with the ISMP.

6.2.2 Storm Sewer Excavation Work (254 Maspeth Avenue)

GFE, on behalf of Cooper Tank, notified NYSDEC and National Grid of planned storm sewer construction activities at the 254 Maspeth Ave property as required by the ISMP. The surface intrusive work was conducted over a two-week period beginning May 29, 2013 and ending June 19, 2013 at the Site in accordance with the approved ISMP and included:

- Excavation and stockpiling of Site soils for reuse.
- Excavation and off-site disposal of impacted soils encountered during storm sewer installation based on field/visual observations.

JRM was selected by Cooper Tank to serve as the contractor to excavate and install the storm sewer system for the 254 Maspeth Avenue parcel. AECOM served as the Site engineer and provided the day to day oversight of the contractor and managed the Community Air Monitoring Program. Excavated materials that were identified through visual and olfactory screening methods were transported off-site in permitted dump trucks to the receiving facility (Bayshore Soil Management LLC) under proper manifest. Excavated materials that were identified as clean based on visual and

olfactory screening methods were reused on-site for backfilling or grading purposes. All work was conducted in accordance with the ISMP.

6.3 IRM - Shallow Soil Excavation

This section summarizes the remedial activities completed as part of the IRM for Shallow Soil Excavation. A detailed accounting of all the activities involved in the work is provided in the *Shallow Soil Interim Remedial Measure Completion Report* (AECOM, 2014), included in Appendix N.

In 2011, the operator of the facility at 254 Maspeth Avenue (Cooper Tank) was in the process of obtaining a NYSDEC Part 360 Permit for operating a recycling facility. This permit would expand the waste recycling / waste transfer station at 222 Maspeth Avenue onto the 252 and 254 Maspeth Avenue properties, and it required construction of a minimum 8-inch thick concrete pad across the entire surface of the Site, a storm water collection system, and a 30-foot high wall along the perimeter of the 254 Maspeth Avenue property. These activities were expected to be invasive and could encounter environmentally impacted materials observed during the ongoing RI activities. As a result, National Grid and the NYSDEC agreed that an IRM would be conducted on the 254 Maspeth Avenue property to remove visual impacts above the groundwater surface. The objectives of this IRM were to:

- Remove, to the extent possible, visual impacts observed in soils above the water table (or to a minimum depth of 5 ft bgs if the water table is shallower) on the 254 Maspeth Avenue property.
- Provide a safe working environment during the proposed redevelopment of the 254 Maspeth Avenue property.

Visually impacted soils were being targeted for the IRM, as they were identified as sources that were readily recoverable. Cooper Tank stated to National Grid that field activity during the proposed redevelopment would extend to a maximum depth of 5 ft bgs. As such, soils within the limits of the IRM were removed to a minimum depth of 5 ft bgs irrespective of the depth of the water table. Any remaining residual impacts across the 254 Maspeth Avenue property would be accounted for in a Site Management Plan and/or final Remedial Design/ Cleanup Plan for the Site.

In September 2011, a PDI was conducted, as described in Section 3.1.2, to gather additional information needed to ensure a safe and effective design of the IRM, facilitate its implementation, and provide soil pre-characterization for disposal.

The IRM activities were completed in September 2012 in accordance with the NYSDEC approved IRM Work Plan (National Grid, 2011d) and included the following:

- Removal and disposal of select surface and subsurface soils above the groundwater table for off-site thermal treatment.
- Removal of former MGP structures encountered within the excavation footprints.
- Placement of a demarcation fabric at the bottom of the excavations and placement of clean gravel backfill to 3 ft bgs.

EQ Northeast was selected by National Grid to serve as the primary remediation contractor. Based on the soil profile data, Bayshore Recycling, Inc. was able to approve a fast track schedule for accepting soils at their facility for thermal treatment.

The areas excavated are shown in Figure 6-2 and are as follows:

- Soils within Area A were excavated to an approximate depth of 7 to 8 ft bgs. Visibly impacted soil was observed on the northern wall of the excavation at a depth of 4 to 6 ft bgs but could not be removed due to the presence of perimeter fence separating the 254 Maspeth Avenue property and the Fed Ex property. Approximately 37.4 cubic yards (cy) of material was removed from Area A.
- Soils within Area B were excavated to an approximate depth of 5 to 6 ft bgs. Approximately 20.4 cy of material was removed from Area B.
- Soils within Area C was excavated to an approximate depth of 5 to 7 ft bgs. Visibly impacted soil was also observed on the eastern wall of the excavation at a depth of 3 to 5 ft bgs but could not be removed due to the presence of perimeter fence separating the 254 Maspeth Avenue property and the Fed Ex property. Approximately 432 cy of material was removed from Area C.
- Soils within Area D was excavated to an approximate depth of 8 ft bgs. Visibly impacted soil was observed on the southern wall of the excavation at a depth of 3 to 5 ft bgs but could not be removed due to the proximity of the Warehouse building on the 7 Rewe Street property. Approximately 284.8 cy of material was removed from Area D.

Materials removed during the Shallow Soil IRM included soil and fill material, domestic trash, unknown foundations, historic piping, and construction & demolition debris. Former MGP structure walls and foundations are believed to have been encountered during excavation as evidenced by concrete and brick fragments but could not be conclusively identified.

At each excavation, an orange demarcation fabric was placed at the bottom of the excavation. The excavation was backfilled with clean stone backfill to approximately 3 ft bgs following placement of the demarcation fabric (except for Area D which was backfilled to the ground surface), because the Site improvement activities by Cooper Tank involved the excavation of the same areas, so backfill was not required from 0 to 3 ft bgs. Backfill was later provided by Cooper Tank upon completion of their wall foundation construction activities.

6.4 IRM - NAPL Recovery System

This section summarizes the remedial activities completed as part of the IRM for NAPL Recovery. A detailed accounting of all the activities involved in the work is provided in the *Completion Report, Interim Remedial Measure for NAPL Recovery* (AECOM, 2015a), included in Appendix N.

In September 2011, a PDI was conducted, as described in Section 3.1.2, to gather additional information needed to ensure a safe and effective design of the IRM.

Cooper Tank was issued a NYSDEC Part 360 Permit for the expansion of active recycling operations on the 252 and 254 Maspeth Avenue properties. Conditions of that permit required the construction of a perimeter wall around open areas of the 254 Maspeth property and the installation of a concrete pad with a stormwater collection system across the entire surface of the 252 and 254 Maspeth Avenue properties. Since the installation of the wall and concrete pad would significantly limit access to subsurface areas of the Site, NYSDEC requested that National Grid conduct an IRM to control potential migration of NAPL while a final Site remedy is developed through the DER-10 process. The IRM activities included the following:

- Installation of five NAPL recovery wells at appropriate locations within the central areas of the Site to reduce the quantity of NAPL, and at 18 selected perimeter locations to control the potential for off-Site migration.
- On-going measurement and recovery of NAPL that collects in the recovery wells.

6.4.1 System Design and Installation

Twenty-three (23) recovery wells were installed between March 3 to April 10, 2013, five on-Site and 18 along the perimeter of 222, 252 and 254 Maspeth Ave properties. The recovery well locations are shown on Figure 3-2. The perimeter locations were spaced at approximately 18 ft on center, with the exception of the area along the driveway of 254 Maspeth where the presence of a subsurface structure required spacing of approximately 30 ft between the three NAPL recovery wells (RW-6, RW-7 and RW-8). Soil borings were advanced at each of the locations, and soil samples collected for observation. Copies of the boring logs provided in Appendix D. Based on the observations, the bottom of the well screen was set at the bottom of the observed NAPL saturated interval.

All recovery wells had a common design: 6-inch diameter 0.020-inch slot wire wrap stainless steel screens that were 10 or 15 ft in length and a 5-foot long sump to retain collected NAPL. Each location was equipped with the infrastructure (i.e., conduits for electrical service and tubing) for the subsequent automation of NAPL recovery activities, if needed.

A minimum of 24-hours post-installation of the grout, each well was developed using surge and pump procedures to remove drilling fluids and fine-grained material from the sump, well screen, and filter pack. Development water was stored in on-Site frac tanks prior to disposal at an approved off-site facility.

As part of the installation of the system, initial monitoring activities were conducted to provide a preliminary estimate of potential collection rates to determine which locations would require automation for cost-effective management of collected NAPL. Eleven manual monitoring events were conducted from May 2013 to February 2014. The recovery wells were given the following designations based on the volume recovered:

- “Primary Recovery Wells” recovered the majority (approximately 85%) of the NAPL: two interior wells on the 252 Maspeth parcel (RW-2, RW-3), three perimeter wells on the 254 Maspeth parcel (RW-10, RW-12, RW-13), and three perimeter wells on the 252 Maspeth parcel (RW-18, RW-19, RW-20).
- “Secondary Recovery Wells” recovered the approximately 15% of the NAPL: four perimeter wells on the 254 Maspeth parcel (RW-8, RW-9, RW-11, RW-17) and one perimeter well on the 252 Maspeth parcel (RW-21).
- “Gauging Wells” recovered no or limited quantities: three interior wells on the 252 Maspeth Ave property (RW-1, RW-4, RW-5), five perimeter wells on the 254 Maspeth property (RW-6, RW-7, RW-14, RW-15, RW-16), and two perimeter wells on the 222 Maspeth property (RW-22, RW-23).

NAPL was collected during these events and managed at the Tradebe Facility in Cohoes, NY as an alternative fuel in accordance with NYSDEC DER-4 (NYSDEC, 2002a).

The recovery systems for the Primary and Secondary Recovery Wells were automated. The pumps, associated controls and NAPL accumulation tank were installed during the period of June and July 2014.

6.4.2 Operation and Maintenance

The NAPL recovery system is intended to collect NAPL and develop data related to the nature and extent of to support the evaluation of potential long-term remedies for the Site. As a result, the NAPL recovery system is operated in a manner that maintains the NAPL levels within the well sumps.

The primary and secondary locations have been equipped with fixed speed pumps. The well pumps are controlled with timers that are adjusted to ensure that the NAPL is contained within the sump of each well, but at a level above the inlet to the pump to minimize the collection of groundwater. The initial pumping rates for these locations are provided below.

- Primary Recovery Wells – 0.2 gallons per minute (gpm) for approximately 5 minutes per day to achieve a recovery rate of approximately 1 gpd.
- Secondary Recovery Wells- 0.01 to 0.05 gpm for approximately 10 minutes per day to achieve a recovery rate of 0.1 to 0.5 gpd.

Collected NAPL accumulates in a 500 gallon double walled polyethylene capacity tank located above ground in the system's control trailer on the 254 Maspeth Ave parcel. The accumulation tank is equipped with a high liquid level detector to prevent over-filling, as well as secondary containment. The system is also equipped with additional alarms and communication equipment to ensure its safe operation.

The system is exempt from solid and hazardous waste permitting requirements under NYSDEC Guidance DER-10 Technical Guidance for Site Investigation and Remediation (NYSDEC, 2010) and the Consent Order for the Site since the substantive technical requirements of permits is met by the following:

- Development and Implementation of a Preparedness and Prevention Plan, Contingency Plan and Closure Plan.
- Maintaining Secondary Containment on the accumulation tank.

Additionally, the contents of the tank are removed at a frequency of less than 90-days.

The Gauging Wells are monitored during quarterly inspection activities and collected NAPL is recovered using air lift equipment and stored in sealed drums and collected with the NAPL from the accumulation tank.

Accumulated NAPL is collected as required for transport by a licensed contractor to the Tradebe Facility for use as an alternative fuel. Representative samples of the contents of the tank are collected and analyzed as required to support the disposal activities. Samples are submitted for proper waste characterization on an annual basis as required by the disposal facility. An EPA RCRA ID number (NYR 000 225 615) has been obtained to facilitate disposal of the NAPL.

6.4.3 Reporting

The IRM activities are documented in an annual report for the first year of operation and in quarterly Monitoring and Recovery Reports thereafter presenting the results from the on-going monitoring and NAPL recovery activities.

The annual report for the period of July 2014 to May 2015 was submitted to NYSDEC in August 2015 (AECOM, 2015b). Approximately 2,270 gallons of mixed fluids have been collected from the system from July 14, 2014 to June 1, 2015 and managed as an alternative fuel at the Tradebe Facility in Cohoes, N.Y. Observations of the collected material indicate an approximate 70:30 ratio of NAPL to water, providing for an average NAPL collection rate of approximately 5 gallons per day. Figure 6-3 shows the cumulative volume of NAPL recovered through December 2015.

7.0 Qualitative Human Health Exposure Assessment

This section of the RI assesses the potential for exposure to constituents present in impacted soils, groundwater, soil vapor, and indoor air. This assessment identifies the potential release and transport mechanisms for the constituents of concern (COCs), point of exposure and exposure routes, and the receptors that could be exposed to COCs originating from the Site. It is assumed that direct contact with NAPL will pose an unacceptable risk and will not be evaluated as part of the QHHEA. The evaluation follows guidelines specified in the NYSDEC DER-10 Technical Guidance for Site Investigation and Remediation (NYSDEC, 2010).

7.1 Site Setting

The Site is occupied by Cooper Tank Recycling Company and used for heavy manufacturing, recycling and sorting of building materials. The Site is comprised of three lots. On Block 2927, Lot 44, there are presently one enclosed building housing offices and one open building (no walls, with roof) housing waste recycling operations. On Block 2927, Lot 54, there is presently one building used as a maintenance center for equipment. On Block 2927, Lot 57, there is presently a parking area with truck scales used for occasional storage of empty roll-offs and vehicle parking. The buildings are serviced by public utilities including electric, water, and sewer.

The Site is located in a mixed commercial/industrial area of Brooklyn, NY. The Site is bounded by Maspeth Avenue to the north, 300 Maspeth Avenue (FedEx) to the east, a portion of 1 Rewe Street (Fesco) and 7 and 8 Rewe Street (West Terminal, LLC) to the south, and a portion of 1 Rewe Street and Vandervoort Avenue to the west.

The Site is underlain by approximately 15 ft of mostly poorly graded sand, silt, and gravel fill identified by anthropogenic material (coal fragments, ash, concrete slabs, wood pieces, wood fragments, brick fragments, glass, and other urban fill debris). A layer of meadow mat (peat and clay) was observed to be present in all areas of the Site underlying fill in thicknesses typically between 5 and 15 ft. Between the bottom of the meadow mat and the top of the Gardiners Clay are units of glacial outwash dominated by sands and silts. The Gardiners Clay is present beneath all areas of the Site and was observed to be 97 ft thick at one Site boring (SB-20J). The Gardiners Clay, a regional confining clay unit, is comprised of a high plasticity, stiff, gray clay and silty clay. Bedrock comprised of gneiss and schist was encountered at one soil boring at 192 ft bgs. Groundwater is encountered beneath the Site at minimum depths of approximately 7 to 8 ft bgs. Shallow groundwater flow has been documented to flow in to the east and southeast in the eastern portion of the Site and to the south in the western portion of the Site. The intermediate groundwater flow has been documented to flow from the north and south on the western portion of the Site to the southeast. The deep groundwater flows to the east and southeast across the Site. The nearest water body in the direction of groundwater flow is the English Kills tributary of Newtown Creek located southeast of the Site.

7.2 Exposure Assessment

Exposure is the process by which humans come in contact with constituents in their environment. Humans can be exposed to constituents in a variety of environmental media including surface soil, subsurface soil, soil vapor, groundwater and ambient/indoor air. Exposure to these media can

potentially occur through several routes including ingestion, dermal contact, and inhalation. The exposure assessment identifies likely pathways by which humans are potentially exposed to COCs.

The assessment includes the following:

- Development of a conceptual Site model (CSM)
- Discussion of potential sources
- Evaluation of on-Site and off-Site data using health-based screening criteria
- Discussion of potential release mechanisms
- Identification of potential human receptors and receptor-specific exposure pathways

Commercial and industrial properties in the vicinity of the Site obtain drinking water from municipal sources. Municipal sources in the area obtain water from up-state surface water and not from local groundwater. Therefore, the potential for exposure to Site-derived constituents in drinking water has not been considered further in this assessment as it is not considered likely to be a complete exposure pathway.

Figure 7-1 presents the CSM for potential release and transport mechanisms for COCs at the Site. Included on the figure is information regarding the known or potential sources of COCs at the Site, the identified release mechanisms, and the affected source media. Potential migration pathways, exposure media and the potential exposure routes have also been presented. It should be noted that the exposure routes are considered potential unless there is an ongoing or documented exposure.

7.2.1 Analytical Summary

Surface soil (2009), subsurface soil (2009, and 2011 through 2015), groundwater (2009, 2012, and 2013) and sub-slab vapor, indoor air and ambient air (2009, 2010, 2011, and 2015) samples have been collected from the Site and adjacent area and analyzed for a range of constituents. Available analytical data were compared to New York State recommended standards and guidance values on a sample-by-sample basis. Comparison tables are presented in Section 5 of this report. The results of these comparisons are summarized below.

7.2.1.1 Surface Soil

Analytical data for surface soil (0 to 0.5 ft bgs) are summarized in Tables 5-3 through 5-5. Benzo(a)pyrene was the only constituent with concentrations above the Industrial Use SCOs. Benzo(a)pyrene concentrations exceed the Industrial Use SCO at SB-5, SB-7 and SB-11 with concentrations ranging from 2.2 to 5.6 mg/kg. VOCs were not detected in the surface soil samples. PAHs, metals, PCBs and pesticides were detected in at least one sample above the Unrestricted Use SCOs but below the Industrial Use SCOs. Subsequent to sampling, the areas where the surface soil samples were collected have been paved.

7.2.1.2 Subsurface Soil

Analytical data for the subsurface soil samples are summarized in Tables 5-6 through 5-10. Only samples that were not excavated are discussed below. For the purposes of this QHHEA, subsurface soils have been divided into those soils between 1 to 15 ft bgs and subsurface soils deeper than 15 ft bgs. This depth division is based on the assumption that intrusive construction activities undertaken at

the Site are likely to occur at depths between 0 to 15 ft bgs, therefore construction workers may be directly exposed to chemical constituents reported in soils between 0 to 15 ft bgs.

Two metals and seven PAHs were detected in subsurface soils between 1 to 15 ft bgs above the Industrial Use SCOs, as follows:

- Arsenic (9 samples: SB-02B[5-5], SB-06B[6-6], SB-12A[10-12.2], SB-17[1-2], SB-19[2-5], SB-20[1-2], SB-30[3-5], T5-SB7[10-11], TP-01[9-9]) concentrations range from 16.5 to 68.8 mg/kg;
- Mercury (SB-41[5-10]) at a concentration of 12.8 mg/kg;
- Benzo(a)anthracene (13 samples: SB-02B[14-16], SB-02B[5-5], SB-13[0-1], SB-13[12-14], SB-14B[11-13], SB-15[12-14], SB-17[1-2], SB-18[4-5], SB-19[2-5], SB-40[9-10], SB-41[5-10], SB-43[8-9], TP-01[9-9]) concentrations range from 13 to190 mg/kg;
- Benzo(a)pyrene (29 samples: SB-02B[14-16], SB-02B[5-5], SB-08[2-3], SB-09[4-5], SB-10[3-4], SB-12A[10-12.2], SB-13[0-1], SB-13[12-14], SB-14A[1-2], SB-14B[11-13], SB-15[12-14], SB-15[3-4], SB-16A[2-3], SB-17[1-2], SB-18[4-5], SB-19[2-5], SB-20[1-2], SB-21[0-5], SB-29[0-5], SB-30[3-5], SB-40[9-10], SB-41[5-10], SB-43[8-9], SB-47[10-14], T5-SB7[10-11], TP-01[12-12], TP-01[9-9], TP-02[8.5-8.5], TP-03[7-7]) concentrations range from 1.6 to 120 mg/kg;
- Benzo(b)fluoranthene (11 samples: SB-02B[5-5], SB-13[12-14], SB-15[12-14], SB-17[1-2], SB-18[4-5], SB-19[2-5], SB-40[9-10], SB-41[5-10], SB-43[8-9], T5-SB7[10-11], TP-01[9-9]) concentrations range from 11.8 to 130 mg/kg;
- Chrysene (TP-01[9-9]) at a concentration of 140 mg/kg;
- Dibenz(a,h)anthracene (13 samples: SB-02B[14-16], SB-02B[5-5], SB-13[12-14], SB-15[12-14], SB-17[1-2], SB-18[4-5], SB-19[2-5], SB-21[0-5], SB-40[9-10], SB-41[5-10], SB-43[8-9], T5-SB7[10-11], TP-01[9-9]) concentrations range from 1.3 to 9.5 mg/kg;
- Indeno(1,2,3-cd)pyrene (5 samples: SB-17[1-2], SB-40[9-10], SB-41[5-10], SB-43[8-9], TP-01[9-9]) concentrations range from 14 to 48 mg/kg;
- Naphthalene (SB-13[12-14] and TP-01[9-9]) concentrations of 1400 mg/kg and 14000 mg/kg, respectively.

Metals, VOCs (including BTEX), SVOCs (including PAHs), PCBs and pesticides, were detected in at least one sample at a depth between 0 to 15 ft bgs above the Unrestricted Use SCOs but below the Industrial Use SCOs.

The following constituents were detected in subsurface soils deeper than 15 ft bgs, above Industrial Use SCOs:

- Arsenic, lead, manganese, zinc
- Benzene, toluene, xylene
- Acenaphthylene, anthracene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenz(a,h)anthracene, fluoranthene, fluorene, indeno(1,2,3-cd)pyrene, naphthalene, phenanthrene, pyrene

7.2.1.3 Groundwater

Constituents detected in shallow groundwater (from wells screened between 2.5 to 23 ft bgs), at concentrations above AWQSGVs include:

- BTEX
- Other VOCs (acetone, isopropylbenzene, methyl tert-butyl ether, styrene)
- PAHs (acenaphthene, anthracene, benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, fluoranthene, fluorene, indeno(1,2,3-cd)pyrene, naphthalene, phenanthrene, pyrene)
- Other SVOCs (1,1'-biphenyl, 2,4-dimethylphenol, phenol)
- Pesticides (beta-BHC, 4,4'-DDE)
- Metals (antimony, arsenic, beryllium, chromium, copper, iron, lead, magnesium, manganese, mercury, nickel, selenium, sodium, thallium, total cyanide)

Constituents detected in intermediate and/or deep groundwater (from wells screened at greater than 25 ft bgs) at concentrations above AWQSGVs include:

- BTEX
- Other VOCs (1,2-dichloroethane, acetone, chloroform, cis-1,2-dichloroethene, isopropylbenzene, styrene, PCE, trans-1,2-dichloroethene, TCE, vinyl chloride)
- PAHs (acenaphthene, benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, fluorene, indeno(1,2,3-cd)pyrene, naphthalene, phenanthrene)
- Other SVOCs (1,1'-biphenyl, 2,4-dimethylphenol, bis[2-ethylhexyl] phthalate, phenol)
- Metals (arsenic, barium, copper, iron, magnesium, manganese, sodium, total cyanide)

7.2.1.4 Sub-Slab Vapor and Indoor/Ambient Air

Sub-slab vapor and indoor air samples were collected during five sampling events between November 2009 and March 2015. During each event an ambient air sample was also collected. During the first four sampling events (November 2009, March 2010, August 2010 and February 2011) the samples were collected from buildings located on the Site. During the fifth sampling event (March 2015) samples were collected from two buildings adjacent to the Site.

In November 2009, paired indoor air and sub-slab samples were collected from 222 Maspeth Ave and 252 Maspeth Ave. These locations were re-sampled in March 2010. In August 2010 and February 2011, the locations at 222 Maspeth Ave were sampled again. In March 2015, paired indoor air and sub-slab samples were collected from adjacent buildings at 1 Rewe StreetNAV (at the north end and the south end) and 7-9 Rewe Street.

Constituent concentrations detected in indoor air were compared to NYSDOH background indoor air values (NYSDOH, 2006), site-specific outdoor air concentrations, and the paired sub-slab vapor concentrations.

At the on-Site buildings, 15 constituents were detected in at least one indoor air sample at a concentration above NYSDOH's background indoor air values, including:

- 1,2,4-Trimethylbenzene
- 1,3,5-Trimethylbenzene
- 4-Ethyltoluene
- Ethylbenzene
- Hexane
- Naphthalene
- Styrene
- Toluene
- Xylenes
- 2-Butanone
- Carbon tetrachloride
- Chloroform
- Ethanol
- Methylene chloride
- TCE

Ten (10) of these constituents were not detected in the paired sub-slab sample or were detected at a lower concentration in the paired sub-slab sample, including: 1,2,4-trimethylbenzene, 1,3,5-trimethylbenzene, 4-ethyltoluene, hexane, toluene, 2-butanone, carbon tetrachloride, ethanol, methylene chloride, and TCE. Therefore, these constituents are not considered to be from a subsurface source that has migrated to indoor air via the vapor intrusion pathway.

Ethylbenzene, styrene and xylene were detected in the indoor air samples at 222 Maspeth Avenue at concentrations above the NYSDOH indoor air during the November 2009 and August 2010 sampling events. During the November 2009 sampling events, the paired sub-slab concentration was above both the paired indoor air concentrations and the NYSDOH background indoor air values. During the subsequent events (March 2010, August 2010, and February 2011), the sub-slab concentrations at 222 Maspeth Avenue were all lower than the concentrations in the paired indoor air samples and less than NYSDOH indoor air values. Therefore, these constituents are not considered to be from a subsurface source that has migrated to indoor air via the vapor intrusion pathway.

Naphthalene was detected in the indoor air samples at 222 Maspeth Avenue above the NYSDOH background indoor air values with higher concentrations in the paired sub-slab during the November 2009 and March 2010 sampling events. Subsequent to these events, potential vapor migration pathways in this building were sealed and additional indoor air samples were collected during the August 2010 and February 2011 events. These indoor air concentrations were below the NYSDOH background indoor air values.

Chloroform was detected in the indoor air at 222 Maspeth Avenue at concentrations approximately equal to the NYSDOH background concentration in August 2010 and November 2011. It was also detected in sub-slab vapor at a higher concentration than in indoor air during these events. Chloroform was not detected in indoor air in the two sampling events conducted prior to August 2010. Chloroform can be found in products including paint, adhesives, and degreasers known to be present at this location.

In addition at the on-Site buildings, acetone, carbon disulfide, dichlorodifluoromethane, PCE, and trichlorofluoromethane were detected in at least one sub-slab sample at a concentration above the NYSDOH's background indoor air values. However, these constituents were not detected in the paired indoor air sample or were detected at a concentration below the NYSDOH's background values. Therefore, these constituents do not pose a health concern via the vapor intrusion pathway.

In the buildings off-Site on Rewe Street, three constituents (hexane, styrene, and PCE) were detected in at least one indoor air sample at a concentration above NYSDOH's background indoor air values. Hexane was not detected in any of the paired sub-slab vapor samples, therefore, hexane is not considered to be from a subsurface source that has migrated to indoor air via the vapor intrusion pathway. Styrene was detected in the paired sub-slab vapor samples at concentrations approximately equal to or lower than in indoor air. Therefore, styrene is also not considered to be from a subsurface source that has migrated to indoor air via the vapor intrusion pathway. PCE was detected in the paired

sub-slab vapor samples at concentrations lower than in indoor air. Therefore, PCE is also not considered to be from a subsurface source that has migrated to indoor air via the vapor intrusion pathway.

At the off-Site buildings, 1,3-butadiene, 2-butanone, acetone, carbon disulfide, chloroform, dichlorodifluoromethane, ethanol, and trichlorofluoromethane were detected in at least one sub-slab sample above the NYSDOH's background indoor air values. However, these constituents were not detected in the paired indoor air sample or they were detected in the paired indoor air sample at a concentration below the NYSDOH's background indoor air values. Therefore, these constituents do not pose a health concern via the vapor intrusion pathway.

Ambient air samples had concentrations greater than the NYSDOH background indoor air values for nine constituents (1,2,4-trimethylbenzene, 1,3,5-trimethylbenzene, carbon tetrachloride, ethylbenzene, methylene chloride, styrene, PCE, toluene, and TCE). Since the Site is largely paved and the Site is in an industrial area, these elevated concentrations can be attributed to surrounding activities. Therefore, the constituents found in the ambient air are not considered to be from a Site-related subsurface source.

7.2.2 Potential Release Mechanisms

There are several potential release mechanisms by which the constituents detected in soil, groundwater, and soil vapor may be transported to other media. Each mechanism is considered for identified media and potential receptor group. It is assumed that direct contact with NAPL will pose an unacceptable risk and will not be evaluated as part of the QHHEA. Potential release mechanisms for soil include the following:

- Fugitive dust – Constituents detected in surface and subsurface soil could be a potential source for fugitive dust as a result of physical disturbance.
- Volatilization – Volatile constituents detected in surface and subsurface soil may potentially be transported by volatilizing into soil-pore space and eventually emanate -into outdoor or indoor air.
- Leaching – Constituents detected in surface and subsurface soil could potentially leach to groundwater.

Migration of chemical constituents in groundwater can act to transfer Site derived constituents off-Site. There are three mechanisms by which constituents in groundwater can be transported to other media. These migration pathways include the following:

- Adsorption – Constituents in groundwater may be sorbed onto subsurface soils.
- Volatilization – Volatile constituents in groundwater may potentially desorb into soil vapor and be transported into outdoor or indoor air.
- Extraction – Constituents in groundwater may migrate to other media by extraction and use of impacted groundwater.

There are two mechanisms by which volatile constituents in soil vapor can be transported to other media. These migration pathways include the following:

- Migration – Volatile constituents in soil vapor may migrate to indoor air through building foundations (i.e., vapor intrusion to indoor air).
- Migration – Volatile constituents in soil vapor may migrate to other media through soil to outdoor air.

7.2.3 Potential Human Receptors and Exposure Pathways

This section discusses identified potential human receptors and the potentially complete exposure pathways by which receptors may be exposed to Site-derived constituents. The following summary table provides an overview of the current and potential exposure pathways. Each pathway is discussed further below.

Environmental Media & Exposure Route	Human Exposure Assessment
Direct contact with surface soils (and incidental ingestion)	Typically, people are not coming into direct contact with surface soils, because contaminated surface soils are covered with pavement or buildings. People can come into contact with surface soil if they complete ground-intrusive work at the Site.
Direct contact with subsurface soils (and incidental ingestion)	People can come into contact with subsurface soil if they complete ground-intrusive work at the Site.
Ingestion of groundwater	There is no exposure to contaminated groundwater, because the area is served by the public water supply
Direct contact with groundwater	People can come into contact with groundwater if they complete ground-intrusive work at the Site
Inhalation of air (exposures related to soil vapor intrusion) building to prevent the indoor air quality	A soil vapor intrusion evaluation was completed for existing buildings. There is no exposure to soil vapor currently because pathways were sealed on-site. Soil vapor intrusion should be considered in the design of any new construction planned at the Site in the future.

7.2.3.1 Site Receptors

An assessment of potential exposure pathways for receptors in the Site area is presented in Figure 7-1. The analysis includes an identification of each potential receptor group, a listing of each potential exposure media and potential pathway, and a rationale for inclusion or exclusion of each potential receptor in the consideration of remedial actions for the Site where complete or potentially complete pathways exist. Potential receptor groups and potential exposure pathways that may exist for the Site are discussed below.

Site Indoor Industrial Workers

The Site is used for industrial purposes and is zoned for industrial land use. Current land use at the Site is expected to continue in the future. Industrial workers occupy the Site buildings, including full-time indoor workers and intermittent indoor maintenance workers. These workers may be exposed to volatile constituents present in the subsurface of the footprint of the buildings through the migration of impacted vapors to the indoor air of the building. Volatile constituents in sub-slab vapor and indoor air within the Site buildings have been detected above NYSDOH's background indoor air values. Elevated concentrations of naphthalene were detected in one building and potential migration pathways were sealed after the March 2010 sampling event. Subsequent indoor air samples showed

that the potential migration pathway for naphthalene had been effectively addressed. Therefore, inhalation of volatile constituents in indoor air is not considered to be complete for Site industrial workers.

Exposure to groundwater via drinking water is not a complete exposure pathway because the buildings are supplied by a municipal water source, which is derived from surface water sources up-state. Municipal water in the area is not derived from local groundwater.

Direct contact exposure to constituents in soil and groundwater is not considered complete for Site industrial workers because the Site is completely paved or under gravel, and because Site Industrial workers do not conduct intrusive work at the Site and so they are unlikely to directly contact soil and groundwater beneath the Site.

Site Outdoor Industrial Workers

Direct contact exposure to constituents in soil and groundwater is not considered complete for Site industrial workers because the Site is mostly paved, and because Site industrial workers do not conduct intrusive work at the Site and so are unlikely to directly contact soil and groundwater beneath the Site.

Volatile constituents were detected in the ambient air samples collected at the Site. Given the paved nature of the Site and industrial nature of the area, exposure to this ambient air is not considered for the Site.

Site Construction Workers

Constituents have been reported in subsurface soil and groundwater at concentrations in excess of Industrial Use SCOs and AWQSGVs. Outdoor construction workers may potentially be exposed to constituents in subsurface soils and groundwater through direct contact (dermal contact or incidental ingestion) or inhalation of particulates during intrusive construction activities.

Impacted groundwater is present beneath the Site at depths from approximately 7 to 8 ft bgs, making it potentially available for contact by a construction worker. Only properly trained field personnel should complete the subsurface utility work in this area using methods specified in a Site-specific HASP and in the ISMP until the area has been cleared of impacted soils and groundwater.

Site Visitors and Trespassers

The Site is covered almost entirely with impermeable surfaces and large industrial or commercial buildings therefore direct contact with the subsurface is unlikely for Site visitors and trespassers.

These receptors are unlikely to conduct intrusive work in the area, therefore, direct contact with reported constituents in subsurface soils and groundwater is not considered to be a complete exposure pathway.

Volatile constituents were detected in the ambient air samples collected at the Site. Given the paved nature of the Site and industrial nature of the area, exposure to this ambient air is not considered for the Site.

7.2.3.2 Off-Site Receptors

Potential off-Site receptor groups and potential exposure pathways for off-Site areas are discussed below. Analysis of each potential receptor group, potential media and pathways, and a rationale for inclusion or exclusion of each potential receptor in the consideration of remedial actions for the off-Site area have been included.

Off-Site Commercial and Industrial Receptors

The off-Site is covered almost entirely with impermeable surfaces and large industrial or commercial buildings. Industrial and commercial receptors are considered unlikely to conduct intrusive work and therefore direct contact with constituents in soil and groundwater is considered unlikely.

Detected constituents in indoor air samples collected off-Site that were above the NYSDOH background indoor air values are not attributable to soil vapor intrusion. Therefore, exposure to indoor air is not considered for the off-Site commercial and industrial receptors.

Constituents in the ambient air sample collected off-Site were below the NYSDOH background indoor air values and exposure to this ambient air is not considered for the off-Site commercial and industrial receptors.

Off-Site Construction Workers

Constituents have been reported in off-Site surface soil, subsurface soil and groundwater at concentrations in excess of Industrial Use SCOs and AWQSGVs beneath certain portions of the off-Site areas. Outdoor construction workers may potentially be exposed to constituents in subsurface soils and groundwater through direct contact (dermal contact or incidental ingestion) or inhalation of particulates during intrusive construction activities.

It is recommended that only properly trained field personnel should complete the subsurface utility work in these areas using methods specified in a Site-specific HASP until the area has been cleared of impacted groundwater or if deep excavation (greater than 15 ft bgs) is planned.

7.2.4 Summary of Receptors and Potentially Complete Exposure Pathways

A summary of the environmental media, potential receptors and potentially complete exposure pathways has been provided in the following table. Potential receptors are based on Site use and adjacent site uses, and the potential for future uses and activities (i.e., construction/ utility activities). Potentially complete exposure pathways are identified if a receptor has a current or potential future exposure to impacted media.

Location	Media	Exposure Routes	Indoor Commercial/ - Industrial Worker	Outdoor Commercial/ Industrial Worker	Construction/ Utility Worker	Visitor/Trespasser
Site	Surface Soil	Inhalation (volatiles and particulates) Direct Contact (incidental ingestion, dermal contact)	×	×	✓	×
	Subsurface Soil	Inhalation (volatiles and particulates) Direct Contact (incidental ingestion dermal contact)	×	×	✓	×
	Groundwater	Ingestion Direct Contact	×	×	✓	×
	Soil Vapor	Inhalation	×	×	×	×
	Indoor Air	Inhalation	×	×	×	×
	Ambient Air	Inhalation	×	×	×	×
Off-site	Surface Soil	Inhalation (volatiles and particulates) Direct Contact (incidental ingestion, dermal contact)	×	×	✓	×
	Subsurface Soil	Inhalation (volatiles and particulates) Direct Contact (incidental ingestion, dermal contact)	×	×	✓	×
	Groundwater	Ingestion Direct Contact	×	×	✓	×
	Soil Vapor	Inhalation	×	×	×	×

Note:
× Incomplete Exposure Pathway
✓ Complete Exposure Pathway

7.3 Conclusions

Complete exposure pathways have not been identified for Site and off-Site commercial/industrial workers, visitors and trespassers.

Site and off-Site construction workers who perform excavation work on or adjacent to the Site may potentially be exposed to VOCs, SVOCs, metals and/or pesticides in subsurface soil and groundwater if subsurface excavation work is needed adjacent to or at the Site. Only properly trained field personnel should complete the subsurface work in this area using methods specified in a Site-specific HASP and ISMP until the area has been cleared of impacted soils and groundwater.

8.0 Fish and Wildlife Resources Impact Analysis

The Site was assessed against the Fish and Wildlife Resources Impact Analysis (FWRIA) Decision Key (NYSDEC, 2010; DER-10, Appendix 3C) to determine if a FWRIA is required. Based on this evaluation no FWRIA is required. The decision key and rationale for the selections is provided below.

Appendix 3C Fish and Wildlife Resources Impact Analysis Decision Key	If YES Go to:	If NO Go to:
1. Is the Site or area of concern a discharge or spill event?	13	2
⋮		
13. Does the contamination at the Site or area of concern have the potential to migrate to, erode into or otherwise impact any on-site or off-site habitat of endangered, threatened or special concern species or other fish and wildlife resource? (See #9 for list of potential resources. Contact DEC for information regarding endangered species.)	Section 3.10.1	14
14. No Fish and Wildlife Resources Impact Analysis needed.		

Note:
Potential resources consist of the following: any endangered, threatened or special concern species or rare plants or their habitat; any DEC designated significant habitats or rare NYS Ecological Communities; tidal or freshwater wetlands; stream, creek or river; pond, lake, lagoon; drainage ditch or channel; other surface water feature; other marine or freshwater habitat; forest; grassland or grassy field; parkland or woodland; shrubby area; urban wildlife habitat; and other terrestrial habitat.

The available Site data suggest that releases on the Site are a source of environmental impacts in the subsurface at the Site. Discharges have resulted in subsurface soil and groundwater contamination. NAPL has migrated to the east in the interbedded sand and silt beds above the Intermediate Clay (encountered between 40 and 52 ft bgs). It is currently observed in isolated sand lenses within the depth interval of approximately 25 to 50 ft bgs throughout an approximately 48,200 square foot area beneath the 222, 252, and 254 Maspeth Avenue properties. Although the migration of NAPL has been largely controlled by the heterogeneity of the grain sizes in the finely interbedded sands and silts, the overall migration pathway is controlled by the contours of the various lower conductivity surfaces.

Shallow soil impacts were also observed. There is no defined source of the environmental impacts in the shallow soil. For the purpose of this evaluation, the residual shallow soil impacts are assumed to be the result of discharges or spills that occurred during former or current Site operations or from the past placement of urban fill across the area.

No fish or wildlife resources were observed on the industrial Site or surrounding properties. No environmental resources were identified in the vicinity of the Site using NYSDEC's Environmental Resource Mapper (Figure 8-1) with the exception of SD classified water bodies: Newtown Creek, Maspeth Creek, and the English Kills tributary of Newtown Creek. English Kills is located closest to the Site at a distance of 700 ft. Class SD waters are suitable for fish, shellfish and wildlife survival. Water bodies with this classification may not meet the requirements for fish propagation, because of

natural or manmade conditions. Although the absence of other resources presented in the NYSDEC's Environmental Resource Mapper in the vicinity of the Site does not rule out the presence of potential environmental resources, these findings are consistent with heavily industrialized nature of this portion of Brooklyn, NY and observations at the Site.

The presence of the pavement, buildings and other structures on-Site and off-Site, and the contours of the various lower conductivity surfaces prevent potential ecological receptors from contacting impacted media. The on-Site and off-Site areas where impacted media has been observed (300 Maspeth Avenue (FedEx), 1 Rewe Street (Fesco), and 7 and 9 Rewe Street (West Terminal, LLC)) are largely paved or covered with buildings. The current Site operator, Cooper Tank, plans to expand operation of the 222 Maspeth Avenue facility into the 252 and 254 Maspeth Avenue properties. For this expansion, Cooper Tank is required to construct a minimum 8-inch thick concrete pad across the entire surface of the Site, a storm water collection system, and a 30-foot high wall along the perimeter of the 254 Maspeth Avenue property is required. In 2012, prior to construction, National Grid implemented an IRM, removing residual impacted soil observed in the shallow soil and in other areas where construction was planned. Details of the shallow soil IRM are presented in the Shallow Soil Interim Remedial Measure Completion Report (AECOM, 2014). At this time, the construction of the concrete pad has been completed on 254 Maspeth Avenue by Cooper Tank, as well as the storm water collection system and perimeter walls.

Off-Site migration of NAPL in subsurface soils is limited by the IRM installed between 2013 and 2014 by National Grid. The IRM activities included installation of five NAPL recovery wells at appropriate locations within the central areas of the Site to reduce the quantity of NAPL; installation of 18 recovery wells at selected perimeter locations; and measurement and recovery of NAPL that collects in the recovery wells. Operation of the NAPL recovery system is on-going. More information on the NAPL recovery system is available in the Completion Report, Interim Remedial Measure for NAPL Recovery (AECOM, 2015a) provided in Appendix N.

No potential means for on-Site or off-Site impacted media which is related to the Site to migrate to, erode into, or otherwise impact, any potential on-Site or off-Site environmental resources were identified. The impacted media is located beneath barriers (pavement, buildings, and other structures). In addition, the extent of NAPL has been delineated and is limited to on-Site and immediately adjacent off-Site areas and its migration is being further limited by the NAPL recovery system. Therefore, no FWRIA is required.

9.0 Conceptual Site Model

The Conceptual Site Model (CSM) developed for the Site summarizes the physical, chemical, and biological processes that influence the release and migration of contaminants in all Site media (soil, groundwater, and soil vapor) while describing the potential for environmental or human receptor exposure. The CSM was developed early during the RI process and refined as more data were available to direct subsequent rounds of investigation and to support remedial decisions including the completion of two IRMs at the Site.

9.1 Source Areas and Contaminant Migration Pathways

The evaluation of the history and use of the RI Study Area demonstrated the potential for environmental impacts from a number of industrial and manufacturing sources that used feedstocks or managed products that have similar physical and/ or chemical characteristics as those associated with the MGP process. As a result, the data collected during the RI, and summarized below, may not clearly identify a specific historic, or on-going source.

9.1.1 NAPL and Soils

Based on Site history and RI findings, the No. 1 Relief holder and adjacent structures on the 222 Maspeth Avenue parcel and the western edge of the 254 Maspeth Avenue parcel including the tar tank and settling tank, drip tanks, and separator were identified as the primary source areas for both NAPL and dissolved phase chemicals in the groundwater (Figure 2-4). A lesser amount of impacts were noted in the western portion of the 254 Maspeth Avenue parcel near the former No. 1 and No. 2 Oil Tanks, where a small amount (0.1 foot) of lighter-than-water NAPL (LNAPL) was observed in one monitoring well (MW-4A) screened at the water table. The lack of LNAPL observed in nearby water table wells indicated an isolated amount of LNAPL was released in this area.

Releases of NAPL migrated vertically downward through the fill under density driven flow until it reached the former natural ground surface (meadow mat), where portions of it spread laterally to the north and east within or on top of the meadow mat surface. There may be a potential preferential pathway of NAPL above and within the meadow mat beneath the 300 Maspeth Avenue property that roughly aligns with the 1900s-era former water course: however, no obvious channel morphology or noticeable differences in soil permeability were noted in this area compared to nearby areas (Figure 5-2). Despite this finding, it is clear from the data that there was not a significant amount of NAPL present in this area, and that it had a limited potential to migrate east of the RI Study Area based on the residual, i.e. not saturated nature, of impacts documented.

Some of the NAPL released migrated vertically under density driven flow into the underlying more permeable glacial outwash sands, where it pooled on first confining unit (identified in this RI as the intermediate clay later) and spread laterally to the east and to a lesser extent to the north and south closely aligning with the topography of the top of the intermediate clay unit (from higher elevations to lower elevation areas) (Figure 5-3). The intermediate clay unit pinches out under the 222 Maspeth Avenue parcel roughly mid-way beneath the former No. 1 Relief Holder (Figure 4-9) and is not present at borings advanced west of this area.

The absence of the confining intermediate clay allowed portions of the released NAPL to migrate vertically downward past the edge of the pinched out intermediate clay unit under density driven flow through the glacial outwash sands until it reached the next confining or semi-confining layer below the intermediate clay, which was identified in this RI and the lower clay lens. The lower clay lens is a discontinuous clay unit observed in a subset of borings beneath the 222, 252, and western portion of the 254 Maspeth Avenue parcels, and extending to the north onto the Greenpoint property and to the south beneath 1 Rewe Street and the western portion of 7-9 Rewe Street. NAPL collecting above this surface followed the topography of the surface (from higher to lower elevations) and was responsible for the presence of NAPL in the former dust suppression well (PW-1) located at the 222 Maspeth Avenue parcel (Figure 5-4). Similar to the intermediate clay unit, the lower clay lens is absent in the western portion of the 222 Maspeth Avenue parcel.

The absence of the lower clay lens beneath a portion of the 222 Maspeth Avenue parcel allowed some of the released NAPL to migrate vertically downward past the edges of the pinched out intermediate clay and lower clay lenses to the top of the next confining unit below the lower clay lens, which was identified as the Gardiners Clay (Figure 5-5). The Gardiners Clay is a regional confining unit in the area. As the NAPL continued to migrate further from its source, the volume of the NAPL and the driving head of the NAPL decreased. As a result, the least amount of NAPL was observed at the top of the Gardiners Clay surface. Where present, NAPL presence aligned with the topography of the top of the Gardiners Clay surface. NAPL was observed in one boring southwest of former Relief Holder No. 1 (MW-1C) downslope from the holder area based on the top of the Gardiners Clay topography, one boring north of and downslope the holder (SB-27), and two borings east of and downslope from the holder (SB-29 and SB-22). The presence of NAPL at SB-22 is interpreted to be the result of the lower clay lens pinching out in close proximity to the boring at a location that correlates to a topographic high in the Gardiners Clay such that any NAPL perching on the lower clay lens in this area would migrate to the top of the Gardiners Clay in this area, as illustrated when comparing Figures 5-4 and 5-5. The deepest NAPL impacts were noted above the Gardiners Clay contact at a depth of 100 ft bgs (elevation -81.5 ft NAVD88) at boring SB-27.

The majority of the released NAPL was observed above the intermediate clay unit, at typical depths of 45 to 50 ft bgs (elevation -30 to -35 ft NAVD88). This is evidenced by the number of wells above this surface that contained NAPL compared to the other vertical zones as well as the recoverability characteristics of the NAPL from these wells compared to NAPL removed from wells screened at shallower (above the meadow mat) or deeper zones (above the lower clay lens or above the Gardiners Clay). As such, NAPL recovery IRM efforts were focused on NAPL present above the intermediate clay unit, as outlined in Section 6.

The extent of observed NAPL-related impacts in soils was determined at all depth intervals during the RI and defined by the following borings completed within the RI Study Area. The lateral extent of impacts is controlled by the topography of the various lower conductivity units beneath the site. A visual depiction of the extent of observed NAPL-related impacts is provided on Figure 5-2 through 5-5.

<u>Above and Within the Meadow Mat</u>

- Borings SB-34, SB-33, SB-35 to the north of the Site
- Borings SB-42, SB-41, SB-31, SB-43, SB-45, SB-44, SB-47, SB-39, T3-SB-series borings, T4-SB-series borings T2-SB4, and T2-SB5 to the south of the Site
- Borings SB-26, SB-25, T2-SB1 through SB-6, SB-38, SB-36T5-SB-3 through SB-8, and T6-series borings to the east of the Site

- Borings SB-6, SB-24, SB-1, SB-23, and SB-32 to the west of the Site

Above the Intermediate Clay Unit

- Borings SB-28, SB-24, SB-35, and GPEC-SB334 to the north of the Site
- Borings SB-1, SB-23, SB-32, SB-42, SB-44, SB-45, SB-39, SB-46, and SB-47 to the south of the Site
- Borings SPEC-SB331, SB-26, SB-4, SB-25, SB-36, SB-37, and SB-38 to the east of the Site
- Borings SB-34, SB-6, SB-24, SB-23, and SB-32 to the west of the Site

Above the Lower Clay Lens Unit

- Borings SB-27, SB-28, SB-33, SB-34, and GPEC-SB333 to the north of the Site
- Borings SB-32, SB-31, SB-21, and SB-39 to the south of the Site
- Borings SB-26, SB-25, SB-36, SB-37, and SB-38 to the east of the Site
- Borings SB-24, SB-1, SB-19, SB-23, and SB-32 to the west of the Site

Above the Gardiners Clay Unit

- Borings SB-34, SB-33, SB-28, and GPEC-SB222 to the north of the Site
- Borings SB-32, SB-31, SB-21, and SB-39 to the south of the Site
- Borings SB-16, SB-26, SB-25, SB-36, SB-37, and SB-38 to the east of the Site
- Borings SB-24, SB-23, and SB-32 to the west of the Site

Given the land use density in the RI Study Area, NAPL and soil impacts are present beyond the Site boundaries. In general, the impacts extend to the north beneath Maspeth Avenue and under a portion of National Grid's Greenpoint Energy Center, to the south beneath the northern portions of the 1 Rewe Street and 7-9 Rewe Street properties, to the west beneath a portion of the 1 Rewe Street property and the sidewalk adjacent to Vandervoort Avenue, and the east beneath portions of the 300 Maspeth Avenue property. As expected, concentrations of BTEX and PAHs in soils decrease significantly or are non-detectable at borings outside the observed extent of NAPL both laterally and vertically.

While utilities are present within the area of identified soil impacts, the shallow depth of utilities compared to the observed depth of impacts minimizes the potential for preferential migration of any impacts along utility corridors. To date, no preferential contaminant migration pathways along utilities has been detected.

No wetlands or ecological habitats are present within the identified area of impacts. There are also no residences, schools, or parks within the identified area of impacts.

9.1.2 Groundwater and Soil Vapor

Groundwater flow beneath the RI Study Area in the shallow, intermediate, and deep overburden aquifer zones is generally to the east and southeast. Influences from pumping at the nearby Brooklyn Truck Wash facility located at 184 Maspeth Avenue have caused localized influences in groundwater flow along the western portion of the Site at intermediate zone wells. Aside from the Brooklyn Truck

Wash, there are no other known users of groundwater in the area adjacent to the Site. All drinking water is supplied by the City.

The highest levels of dissolved BTEX and PAHs in water table wells were noted at GW-1 adjacent to former No. 1 Relief Holder and at MW-4A adjacent to the former No. 1 and No. 2 Oil Tanks (Figure 5-10). Low to non-detect BTEX and PAHs were noted along the western, upgradient portion of the Site. Low to non-detect levels of BTEX and PAHs were also noted at the furthest downgradient wells at 7-9 Rewe Street and 300 Maspeth Avenue downgradient from the Site. Groundwater elevations and gradient data indicate that dissolved phase constituents move downward to the intermediate or deep zones and then move horizontally. Shallow dissolved phase constituents that may be detected at downgradient off-Site areas are more likely attributable to property specific activities and not off-Site migration from the Site based on this finding. In summary, the lower level of impacts in the shallow fill material compared to the deeper zones combined with the strong downward gradients in the water table wells has produced a condition where there is less potential for dissolved phase constituents to migrate off-Site in shallow groundwater.

Furthermore, under part of the Site and adjacent off-Site areas there is also a lower potential for vapor intrusion issues because groundwater concentrations of volatile constituents at the water table are lower than in the deeper portions of the overburden aquifer which contain higher dissolved phase impacts. Volatilization, biodegradation, and dispersion (dilution) of dissolved phase impacts in water table wells would act to further mitigate the potential for vapor intrusion from the subsurface to indoor or ambient air. The soil vapor and indoor air data collected from 252 Maspeth Ave and the buildings on Rewe Street support these findings, as there were no exceedances of the NYSDOH background concentrations. Vapor intrusion sample results from the office structure at 222 Maspeth Ave did show the potential for migration of constituents from soil vapor to indoor air. As a result, remedial actions were taken to seal the identified migration pathways (utility conduits and floor slab opening) into the building as discussed in Section 6.1.

Dissolved phase impacts in the intermediate portion of the overburden aquifer are generally the highest observed at the Site, consistent with this zone containing the most widespread presence of NAPL. Dissolved BTEX and PAHs were highest at on-Site wells MW-5B and MW-7B and decreasing in the direction of groundwater flow towards MW-19B along Rewe Street (Figure 5-11). Decreases in dissolved BTEX and PAHs along the primary groundwater flow path for this interval of the overburden aquifer are the result of advection (i.e., groundwater flow), dispersion, retardation, and biodegradation, as expected. A further decrease of concentrations in downgradient areas outside of the RI Study Area is expected due to the continued effect of these processes. Low (< 100 µg/L) to non-detectable levels of BTEX and PAHs were noted at upgradient wells along Vandervoort Avenue and at downgradient and cross-gradient wells to the east of the Site at FedEx.

Dissolved phase impacts in the deepest portion of the overburden aquifer above the Gardiners Clay are generally consistent with the overlying intermediate zone. Based on upward gradients from the deep to intermediate groundwater zones at the Site, the deep groundwater zone is not expected to be receiving dissolved phase chemicals from the shallow and intermediate zones. Rather the dissolved phase constituents in the deep groundwater zone likely originate from NAPLs that have migrated to the deep formation through flow along seams of higher permeability coupled with density-driven flow. Dissolved BTEX and PAHs were highest at MW-3C and MW-8C within the Site boundary and decreasing in the direction of groundwater flow towards MW-16C along the eastern side of the 300 Maspeth Avenue property (Figure 5-12). Similar to the intermediate overburden portion of the aquifer, decreases in dissolved BTEX and PAHs along the primary groundwater flow path for this interval of

the aquifer are the result of advection (i.e., groundwater flow), dispersion, retardation, and biodegradation, as expected. The hydraulic conductivity in the deep groundwater zone is slightly higher than in the intermediate zone. Low (< 100 µg/L) to non-detectable levels of BTEX and PAHs were noted at upgradient wells along Vandervoort Avenue and at downgradient and cross-gradient wells MW-17C and MW-18C to the east of the Site at FedEx.

9.1.3 Sediments and Surface Water

No sediment depositional areas are present adjacent to the Site. The closest surface water body is the English Kills tributary of Newtown Creek, located approximately 700 ft southeast of the Site. Groundwater from the overburden aquifer, primarily from the intermediate and deeper portions of the aquifer, flows to the east-southeast towards English Kills. No NAPL was observed or detected in any of the downgradient most borings or wells. Any levels of dissolved phase constituents in groundwater discharging to English Kills will be degraded by mixing and biodegradation with surface water.

9.1.4 Ecological and Human Receptors

There is minimal to no risk for ecological receptor impacts at the Site given the lack of habitat, the industrial nature of the RI Study Area, and the transient nature of wildlife in urban areas.

As discussed in Section 7, there are potentially complete pathways for human receptors to come into contact with chemical compounds detected in surface soil, subsurface soil, and groundwater. Potential future construction workers who perform excavation work on or adjacent to the Site may potentially be exposed to contaminants in subsurface soil and groundwater if subsurface excavation work is needed adjacent to or at the Site.

10.0 Summary and Conclusions

This section summarizes the Remedial Investigation findings for the RI Study Area. An overview of the nature and extent of COCs is presented by media and known and potential source areas and migration pathways are identified.

10.1 Site Geology

- Historic fill material covers the majority of the RI Study Area in a layer typically ranging from 15 to 25 ft thick.
- The fill is comprised of mostly poorly graded sand, silt, and gravel with varying amounts of anthropogenic material: coal fragments, ash, concrete slabs, wood pieces, wood fragments, brick fragments, and glass. It can contain elevated levels of PAHs from a variety of urban sources. Other urban fill debris including carpeting and metal scraps consistent with the sites most recent use as a waste transfer station were also encountered.
- In a few isolated locations, a fine sand unit with little silt was observed above the meadow mat, and represented post glacial deposition. The thickness of the unit is less than 10 ft.
- Meadow mat (peat and clay) was observed to be present in all areas of the RI Study Area underlying fill in thicknesses typically ranging up to 4 to 20 ft. The meadow mat represents the former ground surface prior to development (filling) in the site area and is mostly continuous, which is consistent with the historic marshy environment of this area.
- Beneath the bottom of the meadow mat are units of glacial outwash dominated by sands and silts. The sands and silts are identified as the Intermediate Sands. The unit varies in composition, occurring as tan and grey interbedded sand and silt beds and as well graded to poorly graded sands and silt zones. This layer ranges from 5 to 20 ft thick and was generally encountered 20 ft to 30 ft bgs. With depth, the percentages of fines tend to increase.
- Beneath the intermediate sands, the percentages of fines tend to increase until a sharp transition to dense, hard clay with silt and sand lenses, identified as the “Interbedded Clay.” This clayey unit represents a localized confining layer beneath a large portion of the Site footprint. This layer ranges from 19 to 35 ft thick, was generally encountered 36 ft to 52 ft bgs.
- Beneath the Intermediate Clay unit is another sequence of Upper Pleistocene glacial outwash deposits comprised of interbedded sands and silts described as the “Lower Sand” unit. These deposits were documented in all site borings beneath the RI Study Area below the Intermediate Clay unit, beneath the Lower Clay lens, and in areas where the Intermediate Clay unit was absent. This layer ranges from 5 to 10 ft where the intermediate and the low clay units are present to 40 ft thick along the western side of the site. The top of the unit was generally encountered between 46 ft to 80 ft bgs.
- A clay lens labelled the “Lower Clay” lens was identified in several borings within the Lower Sand unit, primarily beneath the 222 and 252 Maspeth Avenue parcels. This lens acts as a localized confining layer where present. This unit ranges from 5 to 10 ft thick and was generally encountered between 78 ft to 86 ft bgs.

- The Gardiners Clay is present beneath all areas of the RI Study Area that were investigated. Lignite is present at the top of the Gardiners Clay at select borings. The unit is comprised of a high plasticity, stiff, blue to greenish gray clay and silty clay. The Gardiners Clay was typically encountered at depths of 80 to 100 ft bgs and was observed to be approximately 97 ft thick at one boring that was advanced through the clay.
- Competent bedrock was encountered at one soil boring at the 222 Maspeth Avenue parcel at a depth of 192.0 ft bgs. The bedrock was comprised of schist identified as the Hartland Schist on the Bedrock and Engineering Geologic Map of New York County and Parts of Kings and Queens Counties, New York (USGS, 1994). There was an observed weathered saprolite zone in the upper 15 ft of bedrock starting at 177 ft bgs showing relic bedrock structures. In general, the bedrock is relatively impermeable, with water transmitted along faults and fractures (Misut and Monti, 1999).

10.2 Site Hydrogeology

- It is estimated that only 15% of precipitation enters the groundwater through recharge in the RI Study Area due to the relatively impervious nature of the RI Study Area surface.
- The surface of the groundwater table was encountered between 5 to 8 ft bgs across the RI Study Area.
- Three groundwater zones beneath the RI Study Area were evaluated during the RI using shallow wells screened across the water table surface in the fill, at depths generally ranging from 5 to 18 ft bgs; intermediate wells screened within sands below the meadow mat at depths generally ranging from 30 to 40 ft bgs; and deep wells screened within the lower sands above the Gardiners Clay unit at general depths from 70 to 80 ft with select wells screened deeper to as required to screen the top of the Gardiners Clay surface.
- Groundwater flows generally from the northwest to the east and southeast under all tidal conditions in all aquifer zones (shallow, intermediate, and deep).
- The deep zone wells beneath the 254 Maspeth Avenue parcel (closest to the English Kills tributary of Newtown Creek) are tidally influenced. No tidal influences were noted in deep wells further to the west beneath the Site.
- Horizontal hydraulic gradients calculated from well gauging ranged from 1.83×10^{-3} ft/ft to 2.6×10^{-2} ft/ft in shallow zone wells, 2.15×10^{-3} ft/ft to 1.22×10^{-2} ft/ft in intermediate zone wells, and 9.88×10^{-4} ft/ft to 6.43×10^{-3} ft/ft in deep zone wells. A generally downward vertical hydraulic gradient is present between shallow zone and intermediate zone wells and a general upward gradient was noted between deep zone wells and intermediate zone wells.
- The average calculated hydraulic conductivity of the shallow, intermediate, and deep zones were 23.8 ft/day, 2.23 ft/day, and 16.0 ft/day, respectively.
- Groundwater seepage velocity estimated in intermediate zone wells ranged from 7.5 to 43 ft/year and from 2.4 to 22.5 ft/year in deep zone wells.

10.3 Nature and Extent of Constituents of Interest

Four media were investigated at the RI Study Area: surface soil, subsurface soil, groundwater, and sub-slab vapor/indoor air. Conclusions for each media are summarized below.

10.3.1 Surface Soil

- Four surface soil samples were collected and analyzed during the RI.
- VOCs, including BTEX, were not detected in the surface soil samples.
- Several PAHs were detected above the Unrestricted Use SCOs but below the Industrial Use SCOs in three of the samples. Total PAH concentrations ranged between 6.03 mg/kg and 92.33 mg/kg in the surface soil samples. Only benzo(a)pyrene was detected in three of the samples at concentrations above its Industrial Use SCO. A few other SVOCs were detected at concentrations below the Unrestricted Use and Industrial Use SCOs.
- Several metals were detected in each surface soil sample at concentrations above the Unrestricted Use SCOs but below the Industrial Use SCOs. Free cyanide was not detected in any of the surface soil samples.
- PCB aroclors were detected above the Unrestricted Use SCO of 0.1 in all of the surface soil samples, ranging from 0.151 mg/kg to 0.258 mg/kg and were below the Industrial Use SCO of 25 mg/kg. Several pesticides were detected in all of the surface soil samples at concentrations above the Unrestricted Use SCOs but below the Industrial Use SCOs. A couple herbicides were detected in each sample but below the Unrestricted Use SCOs. PCBs and pesticides are not associated with MGPs and are interpreted to be related to the presence of urban fill or post-MGP operations.
- The majority of the Site is covered with impervious materials and has been redeveloped since the cessation of MGP operations.

10.3.2 Subsurface Soil

A total of 171 soil samples, including nine duplicate samples, were collected and analyzed from subsurface soils.

- BTEX compounds were detected in many of the subsurface soil samples collected.
  - From 0 to 20 ft bgs, individual BTEX compounds were detected at concentrations above the Unrestricted Use SCOs in 22 of these subsurface soil samples. However, concentrations of individual BTEX compounds were detected above the Industrial Use SCOs in only two of these subsurface samples: SB-10(16-18) and SB-13(18-24). Four VOCs other than BTEX compounds were detected in subsurface soil samples collected from 0 to 20 ft bgs at concentrations above the Unrestricted Use SCOs; however, none of these detections were above the Industrial Use SCOs. Acetone was detected in a number of samples above its Unrestricted Use SCO. In one sample T1-SB7 (16.5-17.5), 1,2-dichlorobenzene, 1,4-dichlorobenzene and chlorobenzene were detected above the Unrestricted Use SCOs.
  - From 20-40 ft bgs, individual BTEX compounds were detected at concentrations above the Unrestricted Use SCOs in 20 of these subsurface soil samples. However, concentrations of individual BTEX compounds were detected above the Industrial Use SCOs in only three of these subsurface samples. Two VOCs other than BTEX compounds were detected in subsurface soil samples collected from 20 to 40 ft bgs at concentrations above the Unrestricted Use SCOs. Acetone was detected in four samples above its Unrestricted Use SCO, and 2-butanone was detected in one sample. However, none of these detections were above the Industrial Use SCOs.

  - From 40 to 60 ft bgs, individual BTEX compounds were detected at concentrations above the Unrestricted Use SCOs in nine of these subsurface soil samples. However, concentrations of individual BTEX compounds were detected above the Industrial Use SCOs in only one of these subsurface samples. No other VOCs other than BTEX compounds were detected in subsurface soil samples collected from 40 to 60 ft bgs at concentrations above the Unrestricted Use SCOs.
  - From greater than 60 ft bgs, individual BTEX compounds were detected at concentrations above the Unrestricted Use SCOs in nine of the subsurface soil samples. However, concentrations of individual BTEX compounds were detected above the Industrial Use SCOs in only two of the subsurface samples. There was only one detection of a VOC other than BTEX compounds (acetone) at a concentration above the Unrestricted Use SCOs, but below the Industrial Use SCOs.

- PAH compounds were detected in many of the subsurface soil samples collected.
  - From 0 to 20 ft bgs, individual PAH compounds were detected at concentrations above the Industrial Use SCOs in 54 of these subsurface samples. An additional four samples had individual PAH concentrations above the Unrestricted Use SCOs but below the Industrial Use SCOs. Seven SVOCs other than PAH compounds were detected in subsurface soil samples collected from 0 to 20 ft bgs at concentrations above the Unrestricted Use SCOs, but only one of these detections was above the Industrial Use SCO (dibenzofuran). Phenolic compounds (including 2-methylphenol, 3-and 4-methylphenol, 4-methylphenol, and phenol) were detected in eight samples from seven locations at concentrations above the Unrestricted Use SCOs. All but one of these locations was located on the Site.
  - From 20-40 ft bgs, individual PAH compounds were detected at concentrations above the Industrial Use SCOs in 14 of these subsurface samples. One additional sample had individual PAH concentrations above the Unrestricted Use SCOs but below the Industrial Use SCOs. Four SVOCs other than PAH compounds were detected in subsurface soil samples at concentrations above the Unrestricted Use SCOs; however, none of these detections were above the Industrial Use SCOs. Phenolic compounds (including 2-methylphenol, 3-and 4-methylphenol, and phenol) were detected in four samples at concentrations above the Unrestricted Use SCOs. Dibenzofuran was detected in seven samples above its Unrestricted Use SCO.
  - From 40 to 60 ft bgs, individual PAH compounds were detected at concentrations above the Industrial Use SCOs in only three of these 28 subsurface samples. One additional sample had individual PAH concentrations above the Unrestricted Use SCOs but below the Industrial Use SCOs. Dibenzofuran was the only non-PAH SVOC compound detected in subsurface soil samples at concentrations above the Unrestricted Use SCOs, and neither of those two detections were above the Industrial Use SCOs.
  - From greater than 60 ft bgs, individual PAH compounds were detected at concentrations above the Industrial Use SCOs in only six of these 27 subsurface samples. No other samples had individual PAH concentrations above the Unrestricted Use SCOs but below the Industrial Use SCOs. No SVOCs other than PAH compounds were detected in subsurface soil samples at concentrations above the Unrestricted or Industrial Use SCOs.

- Total cyanide was detected in seven of the sixteen soil samples analyzed. Detections ranged from 0.16 J mg/kg in SB-29 (0-5) to 27.5 mg/kg in TP-16 (5-6). Only the detection from TP-16(5-6) exceeded the Unrestricted Use SCO of 27 mg/kg, however, this sample location has

since been excavated. Free cyanide was detected in only three of the seventy-two samples analyzed. Detections ranged from 0.75 mg/kg in SB-8 (24-26) to 12.4 mg/kg in SB-13 (18-24). Available cyanide was detected in eight of the seventeen samples analyzed. Detections ranged from 0.055 mg/kg in SB-19 (2-5) to 0.853 J mg/kg in TP-4 (7-7.5). The detected concentrations of free or available cyanide were all below the Unrestricted Use SCO for total cyanide of 27 mg/kg.

- Metals were detected in all of the subsurface soil samples analyzed. Only five metals had soil detections above the Industrial Use SCOs: arsenic, lead, manganese, mercury, and zinc. For arsenic, twenty-three samples had a concentration above the Industrial Use SCO of 16 mg/kg. For lead, only two samples exceeded the Industrial Use SCO of 3,900 mg/kg. For mercury, only two samples exceeded the Industrial Use SCO of 5.7 mg/kg. The only exceedances of the Industrial Use SCOs for manganese and zinc (both are 10,000 mg/kg) came from SB-45 (18-20).
- Pesticides and herbicides were detected in 10 of the 15 subsurface soil samples analyzed. None of the results exceeded the Industrial Use SCOs and none of the detections of herbicides exceeded the Unrestricted Use SCOs. The following pesticides were detected in at least one sample above the Unrestricted Use SCOs but below the Industrial Use SCOs: aldrin, 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, and dieldrin. The pesticide 4,4'-DDT was detected above its Unrestricted Use SCO in the most samples (nine samples).
- PCB aroclors were analyzed in 45 of the subsurface soil samples. Most of these samples were from 20 ft bgs or shallower. PCBs were detected in 15 of those samples with total PCB concentrations ranging from 0.0495 mg/kg in T2-SB4 (5-10) to 5.85 mg/kg in SB-17 (1-2). No Unrestricted Use or Industrial Use SCOs are listed for individual aroclors. All but two of the detections were above the Unrestricted Use SCO for total PCBs but below the Industrial Use SCO. Most of the results above the Unrestricted Use SCOs were from on the Site from the top 5 ft of the subsurface in fill material imported following cessation of MGP operations.
- TPH detections ranged from 52.5 mg/kg [T1-SB8 (17-18.5)] to 17,500 mg/kg [T1-SB7 (22-23)]. The highest detections were from the borings directly east of the former off-Site fuel oil bulk storage area, in the area of the former 10,000 gallon USTs identified on the west side of the FedEx building. DRO was detected in 37 of the 40 samples at concentrations ranging from 13 mg/kg [SB-43 (49-50)] to 160,000 mg/kg [TP-16 (5-6)]. The highest detections were at TP-16 (5-6) (note that this area has since been excavated) and T5-SB2 (18-19) which is located on the east side of the FedEx building near monitoring well MW-16A.
  - Concentrations of DRO were elevated at SB-47(10-14) advanced within the former bulk oil storage facility beneath 9 Rewe Street, consistent with the type of fuels (fuel oil) reportedly stored at that facility.
  - GRO was detected in 18 of the 40 samples at concentrations ranging from 1.9 mg/kg [SB-41(5-10)] to 2,500 mg/kg [SB-40 (20-23.5)].

Results of all subsurface soil sampling indicate a general delineation of constituents of interest both horizontally and vertically across the RI study area. The nature and extent of environmental impacts within the RI Study Area is affected by a number of factors including historic land use and the contribution from surrounding sources. In an area with such a complex history of industrial use, it can be difficult to confirm the origin of delineated impacts, which may be the result of commingled sources in some areas.

10.3.3 Groundwater

During the RI, 38 monitoring wells were installed and sampled. A total of 42 samples, including four duplicate samples, were collected and analyzed. In addition, a sample was collected from the existing on-Site pumping well (PW-1) and groundwater grab samples were collected from two borings (GW-1 and SB-20J) located within the 222 Maspeth Avenue parcel.

Groundwater samples collected beneath and adjacent to the RI Study Area contain compounds at concentrations above the AWQSGVs. These compounds include BTEX, PAHs, cyanide, acetone, isopropyl benzene, chlorinated VOCs, and MTBE. These compounds were detected at varying concentrations in the shallow, intermediate, and deep groundwater zones sampled during the RI.

10.3.3.1 Shallow Zone Wells

- Twelve (12) shallow monitoring wells were installed during the RI. Seven of the 14 shallow groundwater samples contained one or more of the BTEX compounds at concentrations above the AWQSGVs. BTEX compounds were not detected at four locations. Where detected, total BTEX concentrations ranged from 0.13 µg/L (MW-8A) to 15,500 µg/L (GW-1). The highest BTEX concentrations were detected in the vicinity of former No. 1 Relief Holder, the former separator, and the former No. 1 and No. 2 Oil Tanks.
- Six of the 14 shallow groundwater samples contained one or more of the PAH compounds at concentrations above the AWQSGVs. Where detected, total PAH concentrations ranged from 0.82 µg/L (MW-16A) to 36,627 µg/L (GW-1). The highest PAH concentrations were detected in the vicinity of former No. 1 Relief Holder, the former separator, and the former No. 1 and No. 2 Oil Tanks. Of the seventeen PAH compounds, only four PAHs (2-methylnaphthalene, acenaphthylene, benzo(g,h,i)perylene, and dibenzo(a,h)anthracene) were not detected in at least one shallow groundwater sample at concentrations above the AWQSGVs. Naphthalene was detected at the highest concentration in the sample collected from GW-1 (30,000 µg/L).
- Samples from eight of the 12 shallow monitoring wells, and the groundwater grab sample (GW-1), were analyzed for metals. The metals detected at concentrations above AWQSGVs most frequently include iron, magnesium, manganese, and sodium. These metals are not related to MGP operations.
- Samples from the twelve shallow monitoring wells, and the groundwater grab sample (GW-1), were analyzed for total cyanide. Total cyanide was detected in 8 of the 13 shallow groundwater samples and ranged in concentration from 12.1 µg/L (GW-1) to 408 µg/L (MW-4A). Total cyanide was detected at concentrations above the AWQSGV of 200 µg/L in two of the 13 samples at MW-4A and MW-7A.
- Four of the 12 shallow groundwater samples (including one duplicate sample) were analyzed for PCBs during the RI. PCBs were not detected above the reporting limit in any of the four samples analyzed.
- Four of the 12 shallow groundwater samples (including one duplicate sample) were analyzed for pesticides and herbicides during the RI. Three pesticides (beta-BHC, 4,4'-DDD and 4,4'-DDE) were detected in both the primary and duplicate samples from MW-4A. Beta-BHC and 4,4'-DDE were detected above their AWQSGVs in both samples.

10.3.3.2 Intermediate Zone Wells

- Sixteen (16) intermediate monitoring wells were installed during the RI. Twelve (12) of the 15 intermediate groundwater samples contained one or more of the BTEX compounds at concentrations above the AWQSGVs. Where detected, total BTEX concentrations ranged from 15 µg/L (MW-6B) to 33,200 µg/L (MW-5B). The highest BTEX concentrations in the intermediate groundwater zone were detected in the vicinity of the former separator and west of the former No. 1 and No. 2 Oil Tanks, and at MW-19B south of and downgradient of the Site along Rewe Street.
- Five of the 15 intermediate groundwater samples contained one or more chlorinated VOC (cVOC) compounds at concentrations above the AWQSGVs. The highest cVOC concentrations in the intermediate groundwater zone were detected in well MW-2B, which is located on the northern boundary of the Site by Maspeth Avenue. Chlorinated VOCs are not attributable to MGP operations.
- Seven of the 15 intermediate groundwater samples contained one or more of the PAH compounds at concentrations above the AWQSGVs. Where detected, total PAH concentrations ranged from 3.0 µg/L (MW-1B) to 10,056 µg/L (MW-5B). The highest PAH concentrations were detected in the vicinity of the former separator. Naphthalene was detected at the highest concentration in the sample collected from MW-5B (8,500 µg/L).
- A total of 10 intermediate well samples (including one duplicate sample) were analyzed for metals. Several metals were detected at concentrations above the AWQSGVs in intermediate groundwater. The metals detected at concentrations above AWQSGVs most frequently include iron, magnesium, and sodium. These metals are not related to MGP operations.
- All 15 samples from the intermediate monitoring wells (including two duplicate samples) were analyzed for total cyanide. Total cyanide was detected in 11 of the 15 intermediate groundwater samples and ranged in concentration from 11.4 µg/L (MW-2B) to 202 µg/L (MW-5B). Total cyanide was detected at a concentration slightly above the AWQSGV of 200 µg/L in only one sample: MW-5B at 202 µg/L.
- One of the 15 intermediate groundwater samples (MW-1B) was analyzed for PCBs during the RI. PCBs were not detected above the reporting limit in this sample.
- One of the 15 intermediate groundwater samples (MW-1B) was analyzed for pesticides and herbicides during the RI. Pesticides and herbicides were not detected above the reporting limit in this sample.
- Given the trends observed in the data, it is likely that dissolved phase concentrations of these constituents will decrease further at locations outside of the RI Study area due to biodegradation, attenuation, and dilution.

10.3.3.3 Deep Zone Wells

- Twelve (12) deep monitoring wells were installed during the RI and generally screened above the top of the Gardiners Clay. Ten (10) of the 14 deep groundwater samples contained one or more of the BTEX compounds at concentrations above the AWQSGVs. Where detected, total BTEX concentrations ranged from 0.26 µg/L (MW-10C) to 14,870 µg/L (MW-3C). As illustrated on Figure 5-12, the highest BTEX concentrations in the deep groundwater zone were detected on-Site near the pumping well (PW-1 and MW-8C) and east of this area at MW-3C.

- Eleven (11) of the 12 deep groundwater samples contained one or more cVOC compounds at concentrations above the AWQSGVs. The highest cVOC concentrations in the deep groundwater zone were detected in wells MW-4C (located on the eastern boundary of the Site) and MW-16C (located off-Site on the eastern edge of the FedEx property). cVOCs were also detected at elevated levels in the former on-Site pumping well PW-1. Chlorinated VOCs are not attributable to MGP operations
- Eight of the 14 deep groundwater samples contained one or more of the PAH compounds at concentrations above the AWQSGVs. Where detected, total PAH concentrations ranged from 3.0 µg/L (MW-17C) to 3,883 µg/L (PW-1). The highest PAH concentrations in the deep groundwater zone were detected on-Site at or near the former pumping well (PW-1 and MW-8C) and at MW-3C and near the former No. 1 and No. 2 Oil Tanks.
- Ten deep well samples (including one duplicate sample) were analyzed for metals. Several metals were detected at concentrations above the AWQSGVs in deep groundwater, including iron, magnesium, manganese, and sodium. These metals are not related to MGP operations.
- All 14 samples from the deep monitoring wells (including one duplicate sample) were analyzed for total cyanide. Total cyanide was detected in nine of the 14 deep groundwater samples and ranged in concentration from 6.0 µg/L (MW-9C) [estimated] to 100 µg/L (MW-18C). Total cyanide was not detected in any of the deep groundwater samples at a concentration above the AWQSGV of 200 µg/L.
- Two of the 14 deep groundwater samples (MW-1C and MW-3C) were analyzed for PCBs during the RI. PCBs were not detected above the reporting limit in these samples.

Two of the 14 deep groundwater samples (MW-1C and MW-3C) were analyzed for pesticides and herbicides during the RI. Pesticides and herbicides were not detected above the reporting limit in these samples.

The dissolved-phase impacts are the result of a number of factors including geologic conditions, groundwater flow patterns and the presence of source material in soil. The source material in the RI Study Area may originate from a number of sources with similar characteristics. As a result, the dissolved phase impacts may be associated with commingled sources.

10.4 Soil Vapor and Indoor Air

Vapor intrusion sampling was conducted at four properties on/adjacent to the Site over five events in 2009, 2010 (two events), 2011, and 2015. Four rounds of samples were collected from 222 Maspeth Ave, two rounds were collected from 252 Maspeth Ave, and one round was collected from both 1 Rewe Street and 7-9 Rewe Street. At each location a pair of sub-slab vapor and indoor air samples was collected, along with one outdoor ambient air sample per event. The results were compared to published NYSDOH background concentrations.

At 222 Maspeth Ave, four rounds of vapor intrusion evaluation sampling were conducted. The samples were collected from the ground floor (locker room area) of the office structure. The initial two rounds of sampling showed that naphthalene was detected in the indoor air sample from the locker room above background concentrations. It was also detected in the sub-slab vapor samples during these events at concentrations higher than the indoor air sample. Based on the sampling results, it was concluded that the naphthalene may be migrating into the locker room from below the floor slab. Subsequently, potential pathways for sub-slab vapor migration into the locker room were identified, including a previously unknown gap around a sewer cleanout in the locker room floor and unknown

smaller gaps and cracks in the floor of the water meter pit and around conduits entering the water meter pit from the subsurface. These potential pathways were then sealed with cement/concrete and/or non-VOC caulk, and a third and fourth round of vapor intrusion sampling was conducted to verify the effectiveness of the remedial actions. The results of both sampling events showed that naphthalene concentrations detected in indoor air decreased to below background concentrations, indicating that the mitigation of potential pathways was successful.

At 252 Maspeth Ave, two rounds of vapor intrusion evaluation sampling were conducted. The samples were collected from the ground floor of the mechanics shop. In the sub-slab vapor sample, a number of compounds were detected above their NYSDOH background levels; however, in the paired indoor air sample, these compounds were either not detected or detected at a concentration below their NYSDOH background level. Hexane and ethanol were detected in indoor air at concentrations slightly above the NYSDOH background level. An inventory of products in the garage conducted prior to sampling revealed the presence of lacquer thinner, which may have been the source of the hexane detected in indoor air. Ethanol was neither detected in the sub-slab vapor sample nor is it associated with MGPs. After the first set of sampling results were evaluated, it was determined that the indoor air sample was collected during business hours on a week day while work was being conducted in the garage with one of the garage doors open. To ensure that results of the vapor intrusion evaluation were as accurate as possible, an additional round of sampling was conducted during the heating season, with all garage doors closed. No compounds were detected in the indoor air sample at a concentration above the NYSDOH background levels.

At 1 Rewe Street, one set of paired indoor air / sub-slab vapor samples was collected from the north end of the building and one pair from the south end. Only styrene was detected in both the indoor air samples at concentrations above the NYSDOH background level. However, the styrene concentrations in the indoor air samples from the north and south ends of the building were greater than in the paired sub-slab vapor samples. If the vapor intrusion pathway were the source of the styrene, it would be expected to be present in the sub-slab vapor samples at concentrations greater than in the indoor air samples. Styrene is used in many applications including containers, protective packaging, and electronics, which were observed within the building during the pre-sampling survey.

At 7-9 Rewe Street, one set of samples was collected from the north end of the building. Hexane, styrene, and PCE were also detected in the indoor air sample at concentrations above the NYSDOH background levels. However, the indoor air concentrations were higher than in the sub-slab vapor sample. If the vapor intrusion pathway were the source of these compounds, it is expected that concentrations of these compounds would be present in the sub-slab vapor sample at concentrations greater than those in the indoor air sample. In addition, PCE is not an MGP-related compound. The pre-sampling product inventory revealed the presence of multiple products, including adhesive spray, cleaners, diesel fluids, transmission fluids, motor/engine oils, and protective enamels which may be a source of volatile compounds in indoor air.

10.5 Potential Source Areas

Based on visible impacts and subsurface soil analytical results, environmental impacts are present in subsurface soil in the following depth intervals:

1. Within fill above the meadow mat
2. Within silts and sands above the discontinuous intermediate clay unit
3. Within silts and sands above the discontinuous lower clay unit

4. Within silts and sands above the Gardiners Clay, a regional confining unit

The vertical extent of these impacts has been delineated. The horizontal extent of subsurface soil visible impacts has also been delineated. The horizontal extent of subsurface soil analytical results above industrial use SCOs has generally been delineated. The data from the RI may not clearly identify a specific historic, or on-going, source of these impacts due to the fact that a number of industrial and manufacturing sources in the RI Study Area used feedstocks or managed products that have similar physical and/or chemical characteristics as those associated with the MGP process.

Based on Site history and RI findings, the No. 1 Relief Holder and adjacent structures on the 222 Maspeth Avenue parcel and the western edge of the 254 Maspeth Avenue parcel including the tar tank and settling tank, drip tanks, and separator were identified as the primary source areas for both NAPL and dissolved phase chemicals in the groundwater. A lesser amount of impacts were noted in the western portion of the 254 Maspeth Avenue parcel near the former No. 1 and No. 2 Oil Tanks. Releases of NAPL migrated vertically downward through the fill under density driven flow until it reached the former natural ground surface (meadow mat), where portions of it spread laterally to the north and east within or on top of the meadow mat surface.

Some of the NAPL released migrated vertically under density driven flow into the underlying more permeable glacial outwash sands, where it pooled on first confining unit (identified in this RI as the intermediate clay later) and spread laterally to the east and to a lesser extent to the north and south closely aligning with the topography of the top of the intermediate clay unit (from higher elevations to lower elevation areas). The intermediate clay unit pinches out under the 222 Maspeth Avenue parcel roughly mid-way beneath the former No. 1 Relief Holder (Figure 4-9) and is not present at borings advanced west of this area.

The absence of the confining intermediate clay allowed portions of the released NAPL to migrate vertically downward past the edge of the pinched out intermediate clay unit under density driven flow through the glacial outwash sands until it reached the next confining or semi-confining layer below the intermediate clay, which was identified in this RI and the lower clay lens. The lower clay lens is a discontinuous clay unit observed in a subset of borings beneath the 222, 252, and western portion of the 254 Maspeth Avenue parcels, and extending to the north onto the Greenpoint property and to the south beneath 1 Rewe Street and the western portion of 7-9 Rewe Street. NAPL collecting above this surface followed the topography of the surface (from higher to lower elevations) and was responsible for the presence of NAPL in the former dust suppression well (PW-1) located at the 222 Maspeth Avenue parcel. Similar to the intermediate clay unit, the lower clay lens is absent in the western portion of the 222 Maspeth Avenue parcel.

The absence of the lower clay lens beneath a portion of the former No. 1 Relief Holder allowed some of the released NAPL to migrate vertically downward past the edges of the pinched out intermediate clay and lower clay lenses to the top of the next confining unit below the lower clay lens, which was identified as the Gardiners Clay. The Gardiners Clay is a regional confining unit in the area. As the NAPL continued to migrate further from its source, the volume of the NAPL and the driving head of the NAPL decreased. As a result, the least amount of NAPL was observed at the top of the Gardiners Clay surface. Where present, NAPL presence aligned with the topography of the top of the Gardiners Clay surface. NAPL was observed in one boring southwest of former Relief Holder No. 1 (MW-1C) downslope from the holder area, one boring north of the holder (SB-27), and two borings east of the holder (SB-29 and SB-22). The deepest NAPL impacts were noted above the Gardiners Clay at 100 ft bgs (-81.5 ft NAVD88) at SB-27.

The majority of the released NAPL was observed above the intermediate clay unit, at typical depths of 45 to 50 ft bgs (elevation -30 to -35 ft NAVD88). This is evidenced by the number of wells above this surface that contained NAPL compared to the other vertical zones as well as the recoverability characteristics of the NAPL from these wells compared to NAPL removed from wells screened at shallower (above the meadow mat) or deeper zones (above the lower clay lens or above the Gardiners Clay). As such, NAPL recovery IRM efforts were focused on NAPL present above the intermediate clay unit. Data collected during the RI demonstrated that NAPL is contained within the RI Study Area.

10.6 Qualitative Human Health Exposure Assessment

The potential for human exposure to constituents present in impacted soils, groundwater, soil vapor, and indoor air was assessed by identifying the potential release and transport mechanisms for the COCs, point of exposure and exposure routes, and the receptors that could be exposed to COCs originating from the Site.

In surface soil, benzo(a)pyrene was the only constituent with concentrations above the Industrial Use SCOs; however, most of the surface soil has either been excavated or paved over. Two metals and seven PAHs were detected above the Industrial Use SCOs in subsurface soils between 1 to 15 ft bgs (the depth to which most intrusive construction activities would be undertaken). These included:

- Arsenic
- Mercury
- Benzo(a)anthracene
- Benzo(a)pyrene
- Benzo(b)fluoranthene
- Chrysene
- Dibenzo(a,h)anthracene
- Indeno(1,2,3-cd)pyrene
- Naphthalene

Constituents detected in shallow groundwater (from wells screened between 2.5 to 23 ft bgs), at concentrations above AWQSGVs include:

- BTEX
- Other VOCs (acetone, isopropylbenzene, methyl tert-butyl ether, styrene)
- PAHs (acenaphthene, anthracene, benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, fluoranthene, fluorene, indeno(1,2,3-cd)pyrene, naphthalene, phenanthrene, pyrene)
- Other SVOCs (1,1'-biphenyl, 2,4-dimethylphenol, phenol)
- Pesticides (beta-BHC, 4,4'-DDE)
- Metals (antimony, arsenic, beryllium, chromium, copper, iron, lead, magnesium, manganese, mercury, nickel, selenium, sodium, thallium, total cyanide)

At the two buildings located on the Site at 222 and 252 Maspeth Avenue, various COCs were detected in sub-slab vapor and indoor air at concentrations above NYSDOH's background indoor air values. In the buildings off-Site at 1 and 7-9 Rewe Street, fewer COCs were detected in sub-slab vapor and indoor air above NYSDOH's background indoor air values.

The relevant receptors identified in the assessment included:

- Site indoor industrial workers
- Site outdoor industrial workers
- Site construction workers
- Site visitors and trespassers
- Off-Site commercial and industrial receptors
- Off-Site construction workers

Site indoor industrial workers may be exposed to volatile constituents present in the subsurface of the footprint of the buildings through the migration of impacted vapors to the indoor air of the building. However, potential migration pathways were sealed as part of after the March 2010 sampling. The subsequent indoor air samples showed that the pathway for naphthalene had been effectively addressed. Therefore, inhalation of MGP-derived volatile constituents in indoor air is not considered to be complete for Site industrial workers.

Direct contact exposure to constituents in soil and groundwater is not considered complete for Site outdoor industrial workers because the Site is mostly paved, and because Site industrial workers are not considered likely to conduct intrusive work at the Site and so are unlikely to directly contact soil and groundwater beneath the Site.

Similarly the off-Site is covered almost entirely with impermeable surfaces and large industrial or commercial buildings. Industrial and commercial receptors are considered unlikely to conduct intrusive work and therefore direct contact with constituents in soil and groundwater is considered unlikely.

The Site is covered almost entirely with impermeable surfaces and large industrial or commercial buildings therefore direct contact with the subsurface is unlikely for Site visitors and trespassers.

Outdoor construction workers (both on-Site and off-Site) may potentially be exposed to constituents in subsurface soils and groundwater through direct contact (dermal contact or incidental ingestion) or inhalation of particulates during intrusive construction activities.

For off-Site indoor air exposure, the two potential MGP-related constituents detected above the NYSDOH background indoor air values are not attributable soil vapor intrusion and exposure to indoor air is not considered for the off-Site commercial and industrial receptors.

Potential MGP-related constituents were detected in the ambient air samples collected at the Site. Given the paved nature of the Site and industrial nature of the area, exposure to this ambient air is not considered for the Site.

Finally, commercial and industrial properties in the vicinity of the Site obtain drinking water from municipal sources. Municipal sources in the area obtain water from up-state surface water and not

from local groundwater. Therefore, the potential for exposure to dissolved constituents in drinking water has not been considered further in this assessment as it is not considered likely to be a complete exposure pathway.

The significant potentially complete exposure pathways identified for both on-Site and off-Site areas were for construction workers for exposure to ambient air (dust), surface and subsurface soil (incidental ingestion and dermal contact) and groundwater (inhalation, incidental ingestion, and dermal contact).

10.7 Fish and Wildlife Resource Impacts Assessment

The Site was assessed against the FWRIA Decision Key (NYSDEC, 2010; DER-10, Appendix 3C) to determine if a FWRIA is required. Based on this evaluation no FWRIA is required. No fish or wildlife resources were observed on the industrial Site or surrounding properties. No environmental resources were identified in the vicinity of the Site using NYSDEC's Environmental Resource Mapper (Figure 8-1) with the exception of SD classified water bodies: Newtown Creek, Maspeth Creek, and the English Kills tributary of Newtown Creek. English Kills is located closest to the Site at a distance of 700 ft.

No potential means for on-Site or off-Site MGP-impacted media which is related to the Site to migrate to, erode into, or otherwise impact, any potential on-Site or off-Site environmental resources were identified. The MGP-impacted media is located beneath barriers (pavement, buildings, and other structures). In addition, the extent of NAPL has been delineated and is limited to on-Site and immediately adjacent off-Site areas and its migration is being limited by the NAPL recovery system.

10.8 Conclusions

The objectives of the RI have been fulfilled and the nature and general extent of environmental impacts at the RI Study Area have been adequately defined. In summary, the extent of NAPL is defined vertically and horizontally within the RI Study Area and does not extend beyond Rewe Street south of the Site towards the closest surface water body, English Kills. The extent of subsurface soil impacts are also generally delineated within these same areas. Dissolved phase groundwater impacts are characterized within the RI Study Area and are lower at downgradient wells compared to the Site. No PCBs were detected in groundwater from any of the wells sampled.

Conditions that would warrant additional IRMs were not observed following completion of the RI. Areas containing environmental impacts are covered by asphalt or developed property and therefore do not pose an immediate risk to receptors as the residuals are isolated from human contact. Potable water in the RI Study Area is provided by the City of New York.

11.0 Recommendations

Following approval of this report by the NYSDEC and NYSDOH, the next step in the process is completion of a Feasibility Study (FS) to evaluate remedial options at portions of the Site where No Further Action (NFA) conditions cannot be established.

In addition, the current Interim Site Management Plan should be maintained for the current property owner/occupant to ensure that potentially complete exposure pathways (e. g., construction worker exposures to soil and groundwater) are properly managed.

Table 2-2
Summary of Historic Use, Properties/Areas Adjacent to the Former Equity Works MGP Site
Former Equity Works MGP Site
Brooklyn, New York

Site	Date	Description	Source
Eastern Abutter			
300 Maspeth Block 2927, Lot 168	1954	Property is cleared and appears vegetated	Aerial
	1966, 1975, 1984, 1994 and 2006	Parking area for trucks, beyond which appears to the a shipping and/or receiving area. Multiple tanks remain on-site, many with leak detection or secondary containment	Aerial EDR Report
Northern Abutter across Maspeth			
285 -287 Maspeth Ave. Greenpoint MGP/Energy Center Block 2837 Lot 1	prior to 1951	Former MGP, with by-product and coking plant operated at the site from 1928 to 1951	EDR Report
	1954, 1966 and 1975	Beyond Maspeth are two MGP plant Tanks and cleared area around the two tanks	
	1964 and 1994	Beyond Maspeth is a baseball field and two MGP plant tanks and MGP plant structures	Aerial
	2001	Gas holders removed	EDR
	2006	Beyond Maspeth is a baseball field and foundations of two former MGP plant tanks and former MGP plant structures. Active PCB facility (tankage >1,100 gal) in 1997. Currently a large quantity generator of RCRA "D', "F", and "U" wastes	Aerial
Southern Abutter			
Southern Abutter Block 2927 Lots 42, 125	1888	Undeveloped	Sanborn
	1907	Only southern portion of site is developed with "J.A. Crombie Co Storage" and "Joseph A Solan saw and planning mill"	Sanborn
	1933	Entire property labeled "Chapman Dock Co" and there is a small road dividing the property. There are small offices and storage structures near what is now Rewe St.	Sanborn
	1951	Still Chapman Dock Co with structures at the southern portion for offices and building material storage	Sanborn
	1965-1981	Southern building identified as Salwen Paper Co. , but southeastern building is labeled "Lack Carpet Co."	Sanborn
	1986-1990	Southern building is still identified as Salwen Paper Co. building, but southeastern building is labeled "Boro recycling"	Sanborn
	1991-1995	Southern building is still identified as Salwen Paper Co., and southeastern building as "shipping"	Sanborn
Western Abutter			
214 Maspeth Ave. Block 2927 Lot 42	1954	Cleared property, beyond which is Vandervoort Ave.	EDR
	1966, 1975, 1984, and 1994	Cleared property that appears to be used as truck parking or a shipping/receiving area	EDR
	2006	Portion of a building that is attached to the southern abutting industrial building (Block 2927, Lot 42)	EDR Report
Block 2090, Lot 30	1888	undeveloped	Sanborn
	1907	Property beyond Vandervoort is labeled "Standard Rope and Twine Co"	Sanborn
	1933	Property is labeled "Lignum Chemical Works", apparently a sawdust processing and storage facility.	Sanborn
	1951	Property appears to used for sawdust processing/storage and metal scrapping	Sanborn
	1965-1995	Part of the property (along Maspeth Ave) continues to be used for metal scrapping, use of the remaining portions are not specified.	Sanborn

Table 2-3
Summary of Environmental Database Search Records, Properties/Areas Adjacent to the Former Equity Works MGP Site
Former Equity Works MGP Site
Brooklyn, New York

Location	Event	Source	
Western Intersection			
Maspeth Ave and Vandervoort Ave	Nov 1998 - Hazmat was called to unknown material on water in the street. The report estimates 60-gallons (assumed organic and water)	EDR Report	NY Spill
	May 2007 - Oil (approx. 5 oz.) was observed coming out of soil in a utility excavation. Subsequently, oil (approx. 1 pint) was observed on water within a utility trench located approx. 100 ft. from the prior observation.	EDR Report	NY Spill
	May 2007 - One pint of oil (unknown petroleum) in trench on 10 gallons of water	EDR Report	NY Spill
	Aug. 2007 - Sheen of unknown petroleum (approx. 1.5 gal) was observed on water (approx. 20 gal) in the bottom of an excavation.	EDR Report	NY Spill
Eastern Abutter			
Federal Express Ex (300 Maspeth)	July 2002 - Tank failure reported	EDR Report	Ltank
	2002- Removal of 20 550-gal gasoline USTs and surrounding soil (900 tons) from site and adjacent property (not identified) in 2002. N Black stained soil with strong petroleum odor observed "adjacent to the southwestern portion of the existing warehouse (not specifically identified)". NFA granted end of 2005/early 2006.	EDR Report	NY Spill
Northern Abutter across			
Brooklyn Union Gate Station - 285 Maspeth Ave.	1981- Liquid Condensate in pipeline found to contain PCB, All "batches" were tested, with off-site disposal	EDR Report	CERC-NFRAP
	Nov. 2003 - Fuel oil spill (1-3 gallons) addressed by in-house staff.	EDR Report	NY Spill
Greenpoint MGP - Energy Center - 287 Maspeth Ave	Nov. 1990 - Gasoline tank (4,000 gal) failed routine leak test (no determined leak rate). Excavated and repaired.	EDR Report	Ltank
	Jan. 1993 - Underground storage tank failed a routing "tightness" test. Vent connections (above level of product) were repaired.	EDR Report	Ltank
	Aug. 1996 - Diesel spill (10 gal) overfill of tank. Remediated		
	March 1998 - Gasoline spill (5 gal), leaking drum. Soil remediated		
	July 2001- Lead base paint debris cleanup from demolition of gas holders	EDR Report	NY Spill
	Sept. 2001- Diesel spill (200 gal), faulty valve on truck. Remediated by contractor and closed.	EDR Report	
	June 2004 - Preliminary site investigation report indicated shallow (0-5 ft. bgs) MGP impacts that were addressed in an Interim Remedial Action. Site impacts were not delineated.	EDR Report	SHWS
Maspeth Avenue	Aug. 2005 - Fuel oil (25 gal) observed in street, cleaned up by sanitation department.	EDR Report	NY Spill
Southern Abutter			
Sigagel Associates 1 Rewe St.	Nov 1996 - Fuel oil (#2) spill from poor housekeeping. UST and soil removed. Closure granted Feb 1998.	EDR Report	NY Spill

Table 2-4
Summary of Historic Use, Former Equity Works MGP Site (222, 252, and 254 Maspeth Avenue, Brooklyn, NY)
Former Equity Works MGP Site
Brooklyn, New York

Date	Description	Source
1880	Site is undeveloped.	Atlas
1886	Site possibly shows a couple features. Unable to distinguish what they are.	Atlas
1888	Site is undeveloped.	Sanborn
1894	Map provides block idendifications. No development features provided.	Atlas
1896	Appears to show Holder No. 1 and Purifier house structure present. Identified as Equity Gas Works.	Atlas DOH
1898	Shows Holder No. 1 AND purifier house structure. Idenfied as Gas Works. Appears to show coal house and oil storage features for No. 1, No. 2, and No. 3 tanks.	Atlas
1903	MGP structures developed, including gas storage holder, relief holder, generator house, purifiers, oil house, and creek	BUG 1903 facility plan
1905	Same as 1903 plan, except relief holder converted to tar tank, drip tank added, oil storage tank added, boiler room expansion	BUG 1905 facility plan
1907	MGP structures include a generator house, purifier house, coal shed, gas holder, tar tank, and oil bunker, coal shed, coad run boiler house, oil storage tanks No. 1, No. 2, and No. 3, sheds, and exhausters.	Sanborn
1915	Holder location details. One holder available with three lifts. One holder in use 1914 and 1915. 430 M.cu.ft, open, tank made of brick, three lifts, foundation was concrete, Laurel Iron Works (builder), built in 1893.	BUG holder details for all sites.
1916	MGP structures include Holder No. 1, relief holder, exhausters, purifier house, coal shed, boilder house, oil storage No. 1 and No. 2 and No. 3	Atlas
1921	Appears to show maximum extent of MGP expansion, all major plant structures and supporting structures shown	BUG 1921 facility plan
1924	MGP structures include Holder No. 1, relief holder, exhausters, purifier house, coal shed, boilder house, oil storage No. 1 and No. 2 and No. 3	Arial
1929	MGP structures (Brooklyn Union Gas Co) include Holder No. 1, relief holder, pump house exhausters, purifier house, sheds, tar tank, coal shed, coal run, boilder house, oil storage No. 1, No. 2, and No. 3.	Atlas
1932	Many MGP structures still present, although holder listed as disconnected and purged, standards removed, and tank partially filled. Creek still present. Six-inch pipe labelled "salt water" shown northwest of holder near Maspeth Avenue (possible well).	BUG 1932 facility plan
1933	The coal shed, gas holder, tar tank and oil bunker are no longer evident and the buildings (generator/purifier houses) are "vacant"	Sanborn
1947	No features/structures present.	Topographic Map, EDR
1951	The site is still listed as owned by Brooklyn Union Gas, but no structures are evident	BUG facility plan
1951	The site listed as sold on September 17, 1951 (handwritten on 1932 BUG facilty plan).	Sanborn
1954	Appears to have storage structures present. No MGP structures.	Aerial, EDR
1956	No features/structures present.	Topographic Map, EDR
1965-1981	No owner listed, storage of used pipe and valves is indicated - three metal clad on wood frame buildings onsite	Sanborn
1966	Appears similar to 1954 Aerial, EDR photograph.	Aerial, EDR
1967	Features/structures present (non MGP related).	Topographic Map, EDR
1975	Appears similar to 1966 Aerial, EDR photograph.	Aerial, EDR
1979	Features/structures present (non MGP related).	Topographic Map, EDR
1984	Appears similar to 1975 Aerial, EDR photograph.	Aerial, EDR
1986-1988	The site appears to be vacant. However, NYC records indicate certificates of occupancy for construction debris transfer activities. Records indicate ownership of separate parcels by Fontana Transfer and Cooper Tank and Welding.	Sanborn
1990-1995	Property labeled as "Garbage Transfer Storage", there is a small one story iron building	Sanborn
1994	Appears similar to 1984 Aerial, EDR photograph.	Aerial, EDR
1995	Features/structures present (non MGP related).	Topographic Map, EDR
2006	Site appears to be in use, similar configuration as 1995. A permitted above ground storage tank (275 gal) for used oil appears to have been in use during the period of 2000 to 2005. Operational as Cooper Tank Recycling to present day.	Aerial, EDR

Table 3-1

	SB-11(32-32.5)100609	10/6/2009	32 to 32.5			
	SB-11(54-56)100609	10/6/2009	54 to 56			

Notes:

* Field duplicate sample collected at this location
VOCs - volatile organic compounds
SVOCs - semivolatile organic compounds
CN - cyanide
PCBs - polychlorinated biphenyls
DRO - Diesel Range Organics
GRO - Gasoline Range Organics
TPH - Total Petroleum Hydrocarbons
TCL - Target Compound List
RCRA - Resource Conservation and Recovery Act
TAL - Target Analyte List
TCLP - Toxicity Characteristic Leaching Procedure
BTEX - benzene, toluene, ethylbenzen, and xylenes
PAHs - polycyclic aromatic hydrocarbons
As - arsenic
Pb - lead
Hg - mercury

Notes:

* Field duplicate sample collected at this location
VOCs - volatile organic compounds
SVOCs - semivolatile organic compounds
CN - cyanide
PCBs - polychlorinated biphenyls
DRO - Diesel Range Organics
GRO - Gasoline Range Organics
TPH - Total Petroleum Hydrocarbons
TCL - Target Compound List
RCRA - Resource Conservation and Recovery Act
TAL - Target Analyte List
TCLP - Toxicity Characteristic Leaching Procedure
BTEX - benzene, toluene, ethylbenzen, and xylenes
PAHs - polycyclic aromatic hydrocarbons
As - arsenic
Pb - lead
Hg - mercury

GRO - Gasoline Range Organics
TPH - Total Petroleum Hydrocarbons
TCL - Target Compound List
RCRA - Resource Conservation and Recovery Act
TAL - Target Analyte List
TCLP - Toxicity Characteristic Leaching Procedure
BTEX - benzene, toluene, ethylbenzen, and xylenes
PAHs - polycyclic aromatic hydrocarbons
As - arsenic
Pb - lead
Hg - mercury

Table 3-2
Soil Vapor, Indoor Air, and Ambient Air Sample Investigation Summary and Rationale
Former Equity Works MGP Site
Brooklyn, New York

Location	Sample Source	Sample Location	Sample ID	Sampling Date
NOVEMBER 2009 Sampling Event [e]				
	Ambient Air	AMB	AMB-111709	11/17/2009
222 Maspeth Ave	Indoor Air	IA-1 [a]	IA-1-111709	11/17/2009
	Soil Vapor	SV-1 [b]	SV-1-111709	11/17/2009
252 Maspeth Ave	Indoor Air	IA-2 [c]	IA-2-111709	11/17/2009
	Soil Vapor	SV-2 [d]	SV-2-111709	11/17/2009
MARCH 2010 Sampling Event				
	Ambient Air	AMB-1	AMB-1	3/14/2010
222 Maspeth Ave	Indoor Air	IA-1 [a]	IA-1	3/14/2010
	Indoor Air	IA-1 [a]	IA-1 Dup	3/14/2010
	Soil Vapor	SV-1 [b]	SV-1	3/14/2010
252 Maspeth Ave	Indoor Air	IA-2 [c]	IA-2	3/14/2010
	Soil Vapor	SV-2 [d]	SV-2	3/14/2010
AUGUST 2010 Sampling Event				
222 Maspeth Ave	Ambient Air	AMB	AMB-1-082810	8/28/2010
	Indoor Air	IA-1 [a]	IA-1-082810	8/28/2010
	Soil Vapor	SV-1 [b]	SV-1-082810	8/28/2010
FEBRUARY 2011Sampling Event				
222 Maspeth Ave	Ambient Air	AMB-1	AMB1	2/12/2011
	Indoor Air	IA-1 [a]	IA1	2/12/2011
	Indoor Air	IA-1-Dup [a]	IA1 DUP	2/12/2011
	Soil Vapor	SV-1 [b]	SS1	2/12/2011
MARCH 2015 Sampling Event				
	Ambient Air	OA-1	OA-1-032515	3/25/2015
1 Rewe St (north end)	Indoor Air	IA-A	IA-A-032515	3/25/2015
	Indoor Air	IA-A	AIR-DUP-032515	3/25/2015
	Soil Vapor	SG-A	SG-A-032515	3/25/2015
1 Rewe St (south end)	Indoor Air	IA-B	IA-B-032515	3/25/2015
	Soil Vapor	SG-B	SG-B-032515	3/25/2015
7-9 Rewe St	Indoor Air	IA-C	IA-C-032515	3/25/2015
	Soil Vapor	SG-C	SG-C-032515	3/25/2015

Notes:
All samples were analyzed for VOCs pls National Grid MGP Indicator Compounds using USEPA Compendium Method TO-15.
Soil vapor samples were also analyzed for helium using ASTM Method D-1946 Modified.
DUP - field duplicate sample

[a] At 222 Maspeth Ave, IA-1 was collected from the ground floor (locker room area) of the office structure.
[b] At 222 Maspeth Ave, SV-1 was collected at the same location as IA-1 from directly below the concrete floor
[c] At 252 Maspeth Ave, IA-2 was collected from the ground floor of the mechanics shop.
[d] At 252 Maspeth Ave, SV-2 was collected at the same location as IA-2 from directly below the concete floor
[e] The samples from November 2009 were also analyzed using NJDEP - SRWM Low Level USEPA TO-15 Method.

Notes:
[a] - GW-1 was a groundwater grab sampled collected on 9/27/2009 from a temporary well constructed in boring SB-14B.
NA - not applicable or not available
NAD 83 - North American Datum of 1983
NAVD 88 - North American Vertical Datum of 1988
ft - feet
bgs - below ground surface

Notes:

NA - Not available
NI - Not installed
NM - not measured
AB - Abandoned
AM - during high tide
PM - during low tide
ft - feet
btoc - below top of casing

DTW = Depth to water from the top of casing/pvc
Some PDI wells (PDI-1 and PDI-3 are screened across multiple zones, groundwater elevation may represent a combination of zones.
Vertical Datum is North American Vertical Datum on 1988 (NAVD88)
[a] Pump in PW-1 shut down on Friday, Jan 8, 2010
[b] The top of casing elevation was not surveyed.
[c] PDI-8 was inaccessible/being advanced during the survey. Two points of rebar were surveyed on either side, adjacent to, the boring location

Notes:
bgs - below groundsurface
ft - feet
NI - Well Not Installed
NA - Not Available / Not Measured
AB - Well Abandoned / Destroyed
NAVD88 - North Americanl Vertical Datum of 1988

* - For water tables wells (A), screen midpoint has been replaced by well water column midpoint.
Negative numbers indicate downward vertical gradients.

Table 5-1
Summary of Remedial Investigation Visible and Olfactory Impacts
Former Equity Works MGP Site
Brooklyn, New York

Boring ID	Property (Address)	Location (On/Off-Site)	Installed By	Completion Date	Ground Surface Elevation NAVD88	Top of impact (ft bgs)	Bottom of Impact (ft bgs)	Impact Code	Impacts - original
SB-1C/MW-1C	Vandervoort Ave	Off-Site	National Grid (AECOM)	11/24/2009	12.86	0	77		None
					12.86	77	78		Moderate to light sheen and naphthalene-like odor
					12.86	78	80		One inch NAPL saturated lenses
					12.86	80	82		NAPL blebs
					12.86	82	82.2		NAPL saturated 1.5 inch lens, residual NAPL, light sheen, naphthalene-like odor

					13.25	2	3		Light naphthalene-like odor
					13.25	3	8		None
					13.25	8	10		Black stained, moderate sheen, moderate naphthalene-like odor
					13.25	10	12		Strong naphthalene-like odor
					13.25	12	15.5		None
SB-16B	254 Maspeth Ave	On-Site	National Grid (AECOM)	10/20/2009	13.25	0	20		None
					13.25	20	23		NAPL coating on plant fibers
					13.25	23	24		None
					13.25	24	26		NAPL coated
					13.25	26	30		NAPL coated with lenses of NAPL saturated
					13.25	30	32		NAPL coated with lenses of NAPL saturated, heavy sheen
					13.25	32	34		NAPL saturated
					13.25	34	34.25		NAPL coated with lenses of NAPL saturated
					13.25	34.25	40		Light/Moderate naphthalene-like odor
					13.25	40	54		None
SB-16C	254 Maspeth Ave	On-Site	National Grid (AECOM)	10/24/2011	12.94	0	1.5		Slight naphthalene-like odor
					12.94	1.5	10		None
					12.94	10	13		Moderate naphthalene-like odor
					12.94	13	15		NAPL coated
					12.94	15	20		Slight naphthalene-like odor, NAPL sheen, small NAPL blebs on bag of water
					12.94	20	23		NAPL coated plant fibers, NAPL and organic-like odors
					12.94	23	25		NAPL coated
					12.94	25	35		Moderate naphthalene-like odor, NAPL coated grains
					12.94	35	36		NAPL saturated, strong naphthalene-like odor
					12.94	36	37.5		Pockets of NAPL saturation
					12.94	37.5	50		Slight naphthalene-like odor
					12.94	50	65		None
					12.94	65	74		Slight/Moderate naphthalene-like odor
					12.94	74	75		Moderate NAPL like odor, NAPL saturated grains
					12.94	75	77.5		NAPL saturated
					12.94	77.5	79		None
					12.94	79	82		NAPL saturated
					12.94	82	85		Lenses of NAPL saturation
					12.94	85	90		None
					12.94	90	95		Moderate naphthalene-like odor
					12.94	95	105		None
SB-7/MW-17B	254 Maspeth Ave	On-Site	National Grid (AECOM)	10/22/2009	12.82	0	8		None
					12.82	8	10		Oily blebs, spotty heavy sheen, fuel-like odor
					12.82	10	17		Oil coating
					12.82	17	18		NAPL saturated lens
					12.82	18	36		None
					12.82	36	38		NAPL saturated beds
					12.82	38	50		none
SB-18	254 Maspeth Ave	On-Site	National Grid (AECOM)	10/6/2009	12.45	0	8		None
					12.45	8	10		Light sheen in tip, moderate naphthalene-like odor
					12.45	10	15.5		Spotty sheen, strong naphthalene-like odor
					12.45	15.5	25.2		None
					12.45	25.2	29.5		Strong naphthalene-like odor
					12.45	29.5	31		None
					12.45	30	31		Moderate naphthalene like odor
					12.45	31	32		Black stained lens, light sheen, naphthalene-like odor
					12.45	32	41		Faint naphthalene-like odor
					12.45	41	42		None
					12.45	42	43.5		Moderate naphthalene-like odor
					12.45	43.5	48		None
					12.45	48	50		Faint naphthalene-like odor
					12.45	50	52		None

TP-2C	254 Maspeth Ave	On-Site	National Grid (AECOM)	9/9/2011	*12.50*	0	2.85	G	None
					12.50	4.5	7.5	Bl	Very slight sheen on ground water
TP-3	254 Maspeth Ave	On-Site	National Grid (AECOM)	10/7/2009	13.12	0	7	G	None
					13.12	7	7.5	LB	Trace odor (petroleum)
TP-4	254 Maspeth Ave	On-Site	National Grid (AECOM)	9/9/2011	*13.00*	0	2	G	None
					13.00	2	4	B	Few hardened NAPL pieces
					13.00	4	6.9	G	None
					13.00	6.9	7.25	Bl	Hydrocarbon-like odor (diesel-like), oil-like material in soil and on groundwater

Notes:
mm = millimeter
(") - inches
(') - feet
NR - No Recovery
ND - Not Documented
ft bgs - feet below ground surface
NAPL - non-aqueous phase liquid
NAVD 88 - North American Vertical Datum of 1988
Ground Surface Elevations in italics are estimated based on neighboring points.

Impact Code Key

R	NAPL Saturated
P	Coated Material, Lenses
O	Blebs, Globs, Sheen
Y	Staining, odor
B	Hardened NAPL
Bl	Petroleum Impacts, Saturation and Sheen
LB	Petroleum Impacts, Staining and odor
G	No Observed Impacts

Notes:

mg/kg - milograms per kilogram

NL - Not Listed

NS - Not Sampled

N - primary sample

FD - field duplicate sample

U = The material was analyzed for but not detected at, or above, the reporting limit. The associated numerical value is the sample quantitation limit.

J = The associated numerical value is an estimated quantity.

UJ = The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

NYSDEC - New York State Department of Environmental Conservation

SVOC - semivolatile organic compound

PAH - polycyclic aromatic hydrocarbons

Bold indicates compound detected at a concentration greater than the reporting limit

Grey highlight indicates exceedance of the NYSDEC PART 375-6 UNRESTRICTED USE standard value

Yellow highlight indicates exceedance of the NYSDEC PART 375-6 INDUSTRIAL and UNRESTRICTED USE standard values

Notes:

mg/kg - milograms per kilogram

NL - Not Listed

N - primary sample

FD - field duplicate sample

NYSDEC - New York State Department of Environmental Conservation

PCB - polychlorinated biphenyls

Bold indicates compound detected at a concentration greater than the reporting limit

Grey highlight indicates exceedance of the NYSDEC PART 375-6 UNRESTRICTED USE standard value

U = The material was analyzed for but not detected at, or above, the reporting limit. The associated numerical value is the sample quantitation limit.

J = The associated numerical value is an estimated quantity.

UJ = The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

NJ = (Organics) The analysis indicates the presence of an analyte that has been "tentatively identified" and the associated numerical value represents its approximate concentration.

Table 5-6
Summary of Subsurface Soil VOC Analytical Results
Former Equity Works MGP Site
Brooklyn, New York

Notes:
mg/kg - milograms per kilogram
N - primary sample
FD - field duplicate sample
ND - Not Detected
NL - Not Listed
NS - Not Sampled
NYSDEC - New York State Department of Environmental Conservation
Bold indicates compound detected at a concentration greater than the reporting limit
Grey highlight indicates exceedance of the NYSDEC PART 375-6 UNRESTRICTED USE standard value
Yellow highlight indicates exceedance of the NYSDEC PART 375-6 INDUSTRIAL and UNRESTRICTED USE standard values
Stippled fill indicates sample location was excavated during subsequent activities at the site.
U - The material was analyzed for but not detected at, or above, the reporting limit. The associated numerical value is the sample quantitation limit.
J - The associated numerical value is an estimated quantity.
UJ - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
D - Detected concentration from diluted analytical run. Concetration corrected for dilution factor.
R - The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet the quality control criteria. The presence of absence of the analyte cannot be verified.
N - (Organics) The analysis indicates the presence of an analyte for which there is presumptive evidence to make a "tentative identification."
NJ - (Organics) The analysis indicates the presence of an analyte that has been "tentatively identified" and the associated numerical value represents its approximate concentration.

Notes:
mg/kg - milograms per kilogram
N - primary sample
FD - field duplicate sample
ND - Not Detected
NL - Not Listed
NS - Not Sampled
NYSDEC - New York State Department of Environmental Conservation
Bold indicates compound detected at a concentration greater than the reporting limit
Grey highlight indicates exceedance of the NYSDEC PART 375-6 UNRESTRICTED USE standard value
Yellow highlight indicates exceedance of the NYSDEC PART 375-6 INDUSTRIAL and UNRESTRICTED USE standard values
Stippled fill indicates sample location was excavated during subsequent activities at the site.
U - The material was analyzed for but not detected at, or above, the reporting limit. The associated numerical value is the sample quantitation limit.
J - The associated numerical value is an estimated quantity.
UJ - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
D - Detected concentration from diluted analytical run. Concetration corrected for dilution factor.
R - The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet the quality control criteria. The presence of absence of the analyte cannot be verified.
N - (Organics) The analysis indicates the presence of an analyte for which there is presumptive evidence to make a “tentative identification.”
NJ - (Organics) The analysis indicates the presence of an analyte that has been “tentatively identified” and the associated numerical value represents its approximate concentration.

Notes:
mg/kg - milograms per kilogram
N - primary sample
FD - field duplicate sample
NL - Not Listed
NS - Not Sampled
NYSDEC - New York State Department of Environmental Conservation
Bold indicates compound detected at a concentration greater than the reporting limit
Grey highlight indicates exceedance of the NYSDEC PART 375-6 UNRESTRICTED USE standard value
Yellow highlight indicates exceedance of the NYSDEC PART 375-6 INDUSTRIAL and UNRESTRICTED USE standard values
Stippled fill indicates sample location was excavated during subsequent activities at the site.
U - The material was analyzed for but not detected at, or above, the reporting limit. The associated numerical value is the sample quantitation limit.
J - The associated numerical value is an estimated quantity.
UJ - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
R - The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet the quality control criteria. The presence of absence of the analyte cannot be verified.

N - primary sample
FD - field duplicate sample
ND - Not Detected
NL - Not Listed
NS - Not Sampled
NYSDEC - New York State Department of Environmental Conservation
Bold indicates compound detected at a concentration greater than the reporting limit
Grey highlight indicates exceedance of the NYSDEC PART 375-6 UNRESTRICTED USE standard value
Yellow highlight indicates exceedance of the NYSDEC PART 375-6 INDUSTRIAL and UNRESTRICTED USE standard values
Stippled fill indicates sample location was excavated during subsequent activities at the site.
U - The material was analyzed for but not detected at, or above, the reporting limit. The associated numerical value is the sample quantitation limit.
J - The associated numerical value is an estimated quantity.
UJ - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
D - Detected concentration from diluted analytical run. Concetration corrected for dilution factor.
R - The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet the quality control criteria. The presence of absence of the analyte cannot be verified.
N - (Organics) The analysis indicates the presence of an analyte for which there is presumptive evidence to make a “tentative identification.”
NJ - (Organics) The analysis indicates the presence of an analyte that has been “tentatively identified” and the associated numerical value represents its approximate concentration.

Table 5-11
Summary of Groundwater VOC Analytical Results
Former Equity Works MGP Site
Brooklyn, New York

Notes:
[1] Guidance or Standard Values - NYSDEC, Division of Water, TOGS (1.1.1) - 6 NYCRR 703.5 [NYSDEC, 1998]. s = Standard Value / g = Guidance Value
[2] Sample GW-1-092709 was collected from a temporary well screen set at SB-14B from 5-15 ft bgs.
[3] Sample SB-20J-081112 collected on 8/11/2012 was a groundwater grab sample from boring SB-20J.
Bold indicates compound detected at a concentration greater than the reporting limit
Shaded/highlighted indicates exceedance of the NYSDEC Groundwater Guidance or Standard Value.
U - The material was analyzed for but not detected at, or above, the reporting limit. The associated numerical value is the sample quantitation limit.
J - The associated numerical value is an estimated quantity.
UJ - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
D - Detected concentration from diluted analytical run. Concetration corrected for dilution factor.
R - The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet the quality control criteria. The presence of absence of the analyte cannot be verified.
ug/L - micrograms per liter
mg/L - milligrams per liter
N - primary sample
FD - field duplicate sample
NL - Not Listed
NA - Not Analyzed
ND - Not Detected
NA - Not Sampled
Shallow zone wells - screen in 0 - 20 ft bgs interval
Intermediate zone wells - screen in 20 - 40 ft bgs interval
Deep zone wells - screen below 60 ft bgs

Notes:

[1] Guidance or Standard Values - NYSDEC, Division of Water, TOGS (1.1.1) - 6 NYCRR 703.5 [NYSDEC, 1998]. s = Standard Value / g = Guidance Value

[2] Sample GW-1-092709 was collected from a temporary well screen set at SB-14B from 5-15 ft bgs.

[3] Sample SB-20J-081112 collected on 8/11/2012 was a groundwater grab sample from boring SB-20J.

Bold indicates compound detected at a concentration greater than the reporting limit

Shaded/highlighted indicates exceedance of the NYSDEC Groundwater Guidance or Standard Value.

U - The material was analyzed for but not detected at, or above, the reporting limit. The associated numerical value is the sample quantitation limit.

J - The associated numerical value is an estimated quantity.

UJ - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

D - Detected concentration from diluted analytical run. Concetration corrected for dilution factor.

R - The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet the quality control criteria. The presence of absence of the analyte cannot be verified.

ug/L - micrograms per liter

N - primary sample

FD - field duplicate sample

NL - Not Listed

ND - Not Detected

NA - Not Sampled

Shallow zone wells - screen in 0 - 20 ft bgs interval

Intermediate zone wells - screen in 20 - 40 ft bgs interval

Deep zone wells - screen below 60 ft bgs

Notes:

[1] Guidance or Standard Values - NYSDEC, Division of Water, TOGS (1.1.1) - 6 NYCRR 703.5 [NYSDEC, 1998]. s = Standard Value / g = Guidance Value

[2] Sample GW-1-092709 was collected from a temporary well screen set at SB-14B from 5-15 ft bgs.

[3] Sample SB-20J-081112 collected on 8/11/2012 was a groundwater grab sample from boring SB-20J.

Bold indicates compound detected at a concentration greater than the reporting limit

Shaded/highlighted indicates exceedance of the NYSDEC Groundwater Guidance or Standard Value.

U - The material was analyzed for but not detected at, or above, the reporting limit. The associated numerical value is the sample quantitation limit.

J - The associated numerical value is an estimated quantity.

UJ - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

D - Detected concentration from diluted analytical run. Concetration corrected for dilution factor.

R - The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet the quality control criteria. The presence of absence of the analyte cannot be verified.

ug/L - micrograms per liter

mg/L - milligrams per liter

FD - field duplicate sample

NL - Not Listed

NA - Not Analyzed

NA - Not Sampled

Shallow zone wells - screen in 0 - 20 ft bgs interval

Intermediate zone wells - screen in 20 - 40 ft bgs interval

Deep zone wells - screen below 60 ft bgs

Notes:

[1] Guidance or Standard Values - NYSDEC, Division of Water, TOGS (1.1.1) - 6 NYCRR 703.5 [NYSDEC, 1998]. s = Standard Value / g = Guidance Value

[2] Sample GW-1-092709 was collected from a temporary well screen set at SB-14B from 5-15 ft bgs.

[3] Sample SB-20J-081112 collected on 8/11/2012 was a groundwater grab sample from boring SB-20J.

Bold indicates compound detected at a concentration greater than the reporting limit

Shaded/highlighted indicates exceedance of the NYSDEC Groundwater Guidance or Standard Value.

U - The material was analyzed for but not detected at, or above, the reporting limit. The associated numerical value is the sample quantitation limit.

J - The associated numerical value is an estimated quantity.

UJ - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

D - Detected concentration from diluted analytical run. Concetration corrected for dilution factor.

R - The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet the quality control criteria. The presence of absence of the analyte cannot be verified.

ug/L - micrograms per liter

N - primary sample

FD - field duplicate sample

NL - Not Listed

ND - Not Detected

NA - Not Sampled

Shallow zone wells - screen in 0 - 20 ft bgs interval

Intermediate zone wells - screen in 20 - 40 ft bgs interval

Deep zone wells - screen below 60 ft bgs

Notes:

[1] Guidance or Standard Values - NYSDEC, Division of Water, TOGS (1.1.1) - 6 NYCRR 703.5 [NYSDEC, 1998]. s = Standard Value / g = Guidance Value

[2] Sample GW-1-092709 was collected from a temporary well screen set at SB-14B from 5-15 ft bgs.

[3] Sample SB-20J-081112 collected on 8/11/2012 was a groundwater grab sample from boring SB-20J.

Bold indicates compound detected at a concentration greater than the reporting limit

Shaded/highlighted indicates exceedance of the NYSDEC Groundwater Guidance or Standard Value.

U - The material was analyzed for but not detected at, or above, the reporting limit. The associated numerical value is the sample quantitation limit.

J - The associated numerical value is an estimated quantity.

UJ - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

D - Detected concentration from diluted analytical run. Concetration corrected for dilution factor.

R - The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet the quality control criteria. The presence of absence of the analyte cannot be verified.

ug/L - micrograms per liter

mg/L - milligrams per liter

FD - field duplicate sample

NL - Not Listed

NA - Not Analyzed

NA - Not Sampled

Shallow zone wells - screen in 0 - 20 ft bgs interval

Intermediate zone wells - screen in 20 - 40 ft bgs interval

Deep zone wells - screen below 60 ft bgs

Notes:

[1] Guidance or Standard Values - NYSDEC, Division of Water, TOGS (1.1.1) - 6 NYCRR 703.5 [NYSDEC, 1998]. s = Standard Value / g = Guidance Value

[2] Sample GW-1-092709 was collected from a temporary well screen set at SB-14B from 5-15 ft bgs.

[3] Sample SB-20J-081112 collected on 8/11/2012 was a groundwater grab sample from boring SB-20J.

Bold indicates compound detected at a concentration greater than the reporting limit

Shaded/highlighted indicates exceedance of the NYSDEC Groundwater Guidance or Standard Value.

U - The material was analyzed for but not detected at, or above, the reporting limit. The associated numerical value is the sample quantitation limit.

J - The associated numerical value is an estimated quantity.

UJ - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte

R - The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet the quality control criteria. The presence of absence of the analyte cannot be verified.

ug/L - micrograms per liter

N - primary sample

FD - field duplicate sample

NL - Not Listed

Shallow zone wells - screen in 0 - 20 ft bgs interval

Intermediate zone wells - screen in 20 - 40 ft bgs interval

Deep zone wells - screen below 60 ft bgs

Notes:

[1] Guidance or Standard Values - NYSDEC, Division of Water, TOGS (1.1.1) - 6 NYCRR 703.5 [NYSDEC, 1998]. s = Standard Value / g = Guidance Value

Bold indicates compound detected at a concentration greater than the reporting limit

Shaded/highlighted indicates exceedance of the NYSDEC Groundwater Guidance or Standard Value.

U - The material was analyzed for but not detected at, or above, the reporting limit. The associated numerical value is the sample quantitation limit.

J - The associated numerical value is an estimated quantity.

UJ - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

D - Detected concentration from diluted analytical run. Concetration corrected for dilution factor.

R - The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet the quality control criteria. The presence of absence of the analyte cannot be verified.

ug/L - micrograms per liter

mg/L - milligrams per liter

N - primary sample

FD - field duplicate sample

NL - Not Listed

ND - Not Detected

Shallow zone wells - screen in 0 - 20 ft bgs interval

Intermediate zone wells - screen in 20 - 40 ft bgs interval

Deep zone wells - screen below 60 ft bgs

Table 5-15
Summary of NAPL Physical Characteristics
Former Equity Works MGP Site
Brooklyn, New York

Well ID	Physical Properties					
	Density (gm/ml)	Viscosity (centipoise)	Surface Tension Air/Water (dynes/cm)	Interfacial Tension NAPL/Water (dynes/cm)*	Surface Tension Air/NAPL (dynes/cm)	Temperature of Measure-ments (^{o}F)
PW-1**	1.0638	33.9	NA	NA	NA	60
MW-3B	1.1072	570	NA	NA	NA	60
MW-14B	NA	NA	NA	NA	NA	NA
MW-15B	1.0945	2840	56.4	17.8	36.2	60
MW-15B	1.0945	2840	56.4	17.8	37.2	60

Notes:
NA - Not Analyzed
gm/ml - grams per milliliter
cm - centimeter
°F - Fahrenheit
ft - feet
ft^2 - feet squared
gal - gallon
gpd - gallons per day
DNAPL - dense non-aqueous petroleum liquid
* This analysis was done with the NAPL on the bottom and water on top, the reverse of the usual process.

Notes are on the last page.

Notes:

All units in micrograms per cubic meter (µg/m³)

[a] Typical non-residential background indoor air concentrations are equal to the 90th percentile values observed by the USEPA in a 2001 study which are the values recommended for comparison in the NYSDOH "Guidance for Evaluating Soil Vapor Intrusion in the State of New York" (NYSDOH, October 2006), Table C2.

[b] At 222 Maspeth Ave, IA-1 was collected from the ground floor (locker room area) of the office structure.

[c] At 222 Maspeth Ave, SV-1 was collected at the same location as IA-1 from directly below the concrete floor slab.

[d] At 252 Maspeth Ave, IA-2 was collected from the ground floor of the mechanics shop.

[e] At 252 Maspeth Ave, SV-2 was collected at the same location as IA-2 from directly below the concrete floor slab.

Bold - Compound detected in a concentration greater than the method reporting limits.

Exceeds NYSDOH NonRes Typical Background Indoor Air

Dup - As suffix on Sample ID indicates that the sample is a field duplicate.

NL - Not listed - data not available for background concentrations for these compounds.

NS: Analyte was not measured.

ND: Analyte was not detected by GC/MS library search.

NA - Not applicable.

U - The compound was analyzed for, but was not detected above the method reporting limit.

J - The analyte was positively identified. The associated numerical value is the approximate concentration of the analyte in the sample.

J+ - The result is an estimated quantity, but the result may be biased high.

UJ - The analyte was analyzed for, but was not detected. The reported quantitation limit is approximated and may be UJ - inaccurate or imprecise.

NJ: Tentatively identified compound, presumptively present at an estimated concentration.

Notes:
All units in micrograms per cubic meter (µg/m³). Typical Background Indoor Air Concentrations (Non-Residential) [a]
[a] Typical non-residential background indoor air concentrations are equal to the 90th percentile values observed by the USEPA in a 2001 study which are the values recommended for comparison in the NYSDOH "Guidance for Evaluating Soil Vapor Intrusion in the State of New York" (NYSDOH, October 2006), Table C2.
[b] At 222 Maspeth Ave, IA-1 was collected from the ground floor (locker room area) of the office structure.
[c] At 222 Maspeth Ave, SV-1 was collected at the same location as IA-1 from directly below the concrete floor slab.
[d] At 252 Maspeth Ave, IA-2 was collected from the ground floor of the mechanics shop.
[e] At 252 Maspeth Ave, SV-2 was collected at the same location as IA-2 from directly below the concrete floor slab.
Bold - Compound detected in a concentration greater than the method reporting limits.
Exceeds NYSDOH NonRes Typical Background Indoor Air
Dup - As suffix on Sample ID indicates that the sample is a field duplicate.
U - The compound was analyzed for, but was not detected above the method reporting limit.
J - The analyte was positively identified. The associated numerical value is the approximate concentration of the analyte in the sample.
UJ - The analyte was analyzed for, but was not detected. The reported quantitation limit is approximated and may be UJ - inaccurate or imprecise

Contact: John Gondek

The Sanborn Library has been searched by EDR and maps covering the target property location as provided by GEI Consultants Inc. were identified for the years listed below. The Sanborn Library is the largest, most complete collection of fire insurance maps. The collection includes maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow, and others. Only Environmental Data Resources Inc. (EDR) is authorized to grant rights for commercial reproduction of maps by the Sanborn Library LLC, the copyright holder for the collection. Results can be authenticated by visiting www.edrnet.com/sanborn.

The Sanborn Library is continually enhanced with newly identified map archives. This report accesses all maps in the collection as of the day this report was generated.

Sanborn® Library search results
Certification # 06C7-4E03-814D

The Sanborn Library includes more than 1.2 million fire insurance maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow and others which track historical property usage in approximately 12,000 American cities and towns. Collections searched:

- ✓ Library of Congress
- ✓ University Publications of America
- ✓ EDR Private Collection

The Sanborn Library LLC Since 1866™

Limited Permission To Make Copies

GEI Consultants Inc. (the client) is permitted to make up to FIVE photocopies of this Sanborn Map transmittal and each fire insurance map accompanying this report solely for the limited use of its customer. No one other than the client is authorized to make copies. Upon request made directly to an EDR Account Executive, the client may be permitted to make a limited number of additional photocopies. This permission is conditioned upon compliance by the client, its customer and their agents with EDR's copyright policy; a copy of which is available upon request.

Disclaimer - Copyright and Trademark notice

This Report contains certain information obtained from a variety of public and other sources reasonably available to Environmental Data Resources, Inc. It cannot be concluded from this Report that coverage information for the target and surrounding properties does not exist from other sources. NO WARRANTY EXPRESSED OR IMPLIED, IS MADE WHATSOEVER IN CONNECTION WITH THIS REPORT. ENVIRONMENTAL DATA RESOURCES, INC. SPECIFICALLY DISCLAIMS THE MAKING OF ANY SUCH WARRANTIES, INCLUDING WITHOUT LIMITATION, MERCHANTABILITY OR FITNESS FOR A PARTICULAR USE OR PURPOSE. ALL RISK IS ASSUMED BY THE USER. EDR Inquiry # 4339741.1

Contact: John Gondek

The Sanborn Library has been searched by EDR and maps covering the target property location as provided by GEI Consultants Inc. were identified for the years listed below. The Sanborn Library is the largest, most complete collection of fire insurance maps. The collection includes maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow, and others. Only Environmental Data Resources Inc. (EDR) is authorized to grant rights for commercial reproduction of maps by the Sanborn Library LLC, the copyright holder for the collection. Results can be authenticated by visiting www.edrnet.com/sanborn.

The Sanborn Library is continually enhanced with newly identified map archives. This report accesses all maps in the collection as of the day this report was generated.

EDR Inquiry # 4339741.1

Contact: John Gondek

The Sanborn Library has been searched by EDR and maps covering the target property location as provided by GEI Consultants Inc. were identified for the years listed below. The Sanborn Library is the largest, most complete collection of fire insurance maps. The collection includes maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow, and others. Only Environmental Data Resources Inc. (EDR) is authorized to grant rights for commercial reproduction of maps by the Sanborn Library LLC, the copyright holder for the collection. Results can be authenticated by visiting www.edrnet.com/sanborn.

The Sanborn Library is continually enhanced with newly identified map archives. This report accesses all maps in the collection as of the day this report was generated.

EDR Inquiry # 4339741.1

Contact: John Gondek

The Sanborn Library has been searched by EDR and maps covering the target property location as provided by GEI Consultants Inc. were identified for the years listed below. The Sanborn Library is the largest, most complete collection of fire insurance maps. The collection includes maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow, and others. Only Environmental Data Resources Inc. (EDR) is authorized to grant rights for commercial reproduction of maps by the Sanborn Library LLC, the copyright holder for the collection. Results can be authenticated by visiting www.edrnet.com/sanborn.

The Sanborn Library is continually enhanced with newly identified map archives. This report accesses all maps in the collection as of the day this report was generated.

EDR Inquiry # 4339741.1

Contact: John Gondek

The Sanborn Library has been searched by EDR and maps covering the target property location as provided by GEI Consultants Inc. were identified for the years listed below. The Sanborn Library is the largest, most complete collection of fire insurance maps. The collection includes maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow, and others. Only Environmental Data Resources Inc. (EDR) is authorized to grant rights for commercial reproduction of maps by the Sanborn Library LLC, the copyright holder for the collection. Results can be authenticated by visiting www.edrnet.com/sanborn.

The Sanborn Library is continually enhanced with newly identified map archives. This report accesses all maps in the collection as of the day this report was generated.

EDR Inquiry # 4339741.1

Contact: John Gondek

The Sanborn Library has been searched by EDR and maps covering the target property location as provided by GEI Consultants Inc. were identified for the years listed below. The Sanborn Library is the largest, most complete collection of fire insurance maps. The collection includes maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow, and others. Only Environmental Data Resources Inc. (EDR) is authorized to grant rights for commercial reproduction of maps by the Sanborn Library LLC, the copyright holder for the collection. Results can be authenticated by visiting www.edrnet.com/sanborn.

The Sanborn Library is continually enhanced with newly identified map archives. This report accesses all maps in the collection as of the day this report was generated.

EDR Inquiry # 4339741.1

Contact: John Gondek

The Sanborn Library has been searched by EDR and maps covering the target property location as provided by GEI Consultants Inc. were identified for the years listed below. The Sanborn Library is the largest, most complete collection of fire insurance maps. The collection includes maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow, and others. Only Environmental Data Resources Inc. (EDR) is authorized to grant rights for commercial reproduction of maps by the Sanborn Library LLC, the copyright holder for the collection. Results can be authenticated by visiting www.edrnet.com/sanborn.

The Sanborn Library is continually enhanced with newly identified map archives. This report accesses all maps in the collection as of the day this report was generated.

EDR Inquiry # 4339741.1

Contact: John Gondek

The Sanborn Library has been searched by EDR and maps covering the target property location as provided by GEI Consultants Inc. were identified for the years listed below. The Sanborn Library is the largest, most complete collection of fire insurance maps. The collection includes maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow, and others. Only Environmental Data Resources Inc. (EDR) is authorized to grant rights for commercial reproduction of maps by the Sanborn Library LLC, the copyright holder for the collection. Results can be authenticated by visiting www.edrnet.com/sanborn.

The Sanborn Library is continually enhanced with newly identified map archives. This report accesses all maps in the collection as of the day this report was generated.

EDR Inquiry # 4339741.1

Contact: John Gondek

The Sanborn Library has been searched by EDR and maps covering the target property location as provided by GEI Consultants Inc. were identified for the years listed below. The Sanborn Library is the largest, most complete collection of fire insurance maps. The collection includes maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow, and others. Only Environmental Data Resources Inc. (EDR) is authorized to grant rights for commercial reproduction of maps by the Sanborn Library LLC, the copyright holder for the collection. Results can be authenticated by visiting www.edrnet.com/sanborn.

The Sanborn Library is continually enhanced with newly identified map archives. This report accesses all maps in the collection as of the day this report was generated.

Sanborn® Library search results
Certification # 06C7-4E03-814D

The Sanborn Library includes more than 1.2 million fire insurance maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow and others which track historical property usage in approximately 12,000 American cities and towns. Collections searched:

- ✓ Library of Congress
- ✓ University Publications of America
- ✓ EDR Private Collection

The Sanborn Library LLC Since 1866™

Limited Permission To Make Copies

GEI Consultants Inc. (the client) is permitted to make up to FIVE photocopies of this Sanborn Map transmittal and each fire insurance map accompanying this report solely for the limited use of its customer. No one other than the client is authorized to make copies. Upon request made directly to an EDR Account Executive, the client may be permitted to make a limited number of additional photocopies. This permission is conditioned upon compliance by the client, its customer and their agents with EDR's copyright policy; a copy of which is available upon request.

Disclaimer - Copyright and Trademark notice

This Report contains certain information obtained from a variety of public and other sources reasonably available to Environmental Data Resources, Inc. It cannot be concluded from this Report that coverage information for the target and surrounding properties does not exist from other sources. NO WARRANTY EXPRESSED OR IMPLIED, IS MADE WHATSOEVER IN CONNECTION WITH THIS REPORT. ENVIRONMENTAL DATA RESOURCES, INC. SPECIFICALLY DISCLAIMS THE MAKING OF ANY SUCH WARRANTIES, INCLUDING WITHOUT LIMITATION, MERCHANTABILITY OR FITNESS FOR A PARTICULAR USE OR PURPOSE. ALL RISK IS ASSUMED BY THE USER. EDR Inquiry # 4339741.1

Contact: John Gondek

The Sanborn Library has been searched by EDR and maps covering the target property location as provided by GEI Consultants Inc. were identified for the years listed below. The Sanborn Library is the largest, most complete collection of fire insurance maps. The collection includes maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow, and others. Only Environmental Data Resources Inc. (EDR) is authorized to grant rights for commercial reproduction of maps by the Sanborn Library LLC, the copyright holder for the collection. Results can be authenticated by visiting www.edrnet.com/sanborn.

The Sanborn Library is continually enhanced with newly identified map archives. This report accesses all maps in the collection as of the day this report was generated.

The Sanborn Library has been searched by EDR and maps covering the target property location as provided by GEI Consultants Inc. were identified for the years listed below. The Sanborn Library is the largest, most complete collection of fire insurance maps. The collection includes maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow, and others. Only Environmental Data Resources Inc. (EDR) is authorized to grant rights for commercial reproduction of maps by the Sanborn Library LLC, the copyright holder for the collection. Results can be authenticated by visiting www.edrnet.com/sanborn.

The Sanborn Library is continually enhanced with newly identified map archives. This report accesses all maps in the collection as of the day this report was generated.

Sanborn® Library search results
Certification # 06C7-4E03-814D

The Sanborn Library includes more than 1.2 million fire insurance maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow and others which track historical property usage in approximately 12,000 American cities and towns. Collections searched:

- ✓ Library of Congress
- ✓ University Publications of America
- ✓ EDR Private Collection

The Sanborn Library LLC Since 1866™

Limited Permission To Make Copies

GEI Consultants Inc. (the client) is permitted to make up to FIVE photocopies of this Sanborn Map transmittal and each fire insurance map accompanying this report solely for the limited use of its customer. No one other than the client is authorized to make copies. Upon request made directly to an EDR Account Executive, the client may be permitted to make a limited number of additional photocopies. This permission is conditioned upon compliance by the client, its customer and their agents with EDR's copyright policy; a copy of which is available upon request.

Disclaimer - Copyright and Trademark notice

This Report contains certain information obtained from a variety of public and other sources reasonably available to Environmental Data Resources, Inc. It cannot be concluded from this Report that coverage information for the target and surrounding properties does not exist from other sources. NO WARRANTY EXPRESSED OR IMPLIED, IS MADE WHATSOEVER IN CONNECTION WITH THIS REPORT. ENVIRONMENTAL DATA RESOURCES, INC. EDR Inquiry # 4339741.1

Contact: John Gondek

The Sanborn Library has been searched by EDR and maps covering the target property location as provided by GEI Consultants Inc. were identified for the years listed below. The Sanborn Library is the largest, most complete collection of fire insurance maps. The collection includes maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow, and others. Only Environmental Data Resources Inc. (EDR) is authorized to grant rights for commercial reproduction of maps by the Sanborn Library LLC, the copyright holder for the collection. Results can be authenticated by visiting www.edrnet.com/sanborn.

The Sanborn Library is continually enhanced with newly identified map archives. This report accesses all maps in the collection as of the day this report was generated.

EDR Inquiry # 4339741.1

Contact: John Gondek

The Sanborn Library has been searched by EDR and maps covering the target property location as provided by GEI Consultants Inc. were identified for the years listed below. The Sanborn Library is the largest, most complete collection of fire insurance maps. The collection includes maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow, and others. Only Environmental Data Resources Inc. (EDR) is authorized to grant rights for commercial reproduction of maps by the Sanborn Library LLC, the copyright holder for the collection. Results can be authenticated by visiting www.edrnet.com/sanborn.

The Sanborn Library is continually enhanced with newly identified map archives. This report accesses all maps in the collection as of the day this report was generated.

EDR Inquiry # 4339741.1

Contact: John Gondek

The Sanborn Library has been searched by EDR and maps covering the target property location as provided by GEI Consultants Inc. were identified for the years listed below. The Sanborn Library is the largest, most complete collection of fire insurance maps. The collection includes maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow, and others. Only Environmental Data Resources Inc. (EDR) is authorized to grant rights for commercial reproduction of maps by the Sanborn Library LLC, the copyright holder for the collection. Results can be authenticated by visiting www.edrnet.com/sanborn.

The Sanborn Library is continually enhanced with newly identified map archives. This report accesses all maps in the collection as of the day this report was generated.

EDR Inquiry # 4339741.1

Contact: John Gondek

The Sanborn Library has been searched by EDR and maps covering the target property location as provided by GEI Consultants Inc. were identified for the years listed below. The Sanborn Library is the largest, most complete collection of fire insurance maps. The collection includes maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow, and others. Only Environmental Data Resources Inc. (EDR) is authorized to grant rights for commercial reproduction of maps by the Sanborn Library LLC, the copyright holder for the collection. Results can be authenticated by visiting www.edrnet.com/sanborn.

The Sanborn Library is continually enhanced with newly identified map archives. This report accesses all maps in the collection as of the day this report was generated.

EDR Inquiry # 4339741.1

Contact: John Gondek

The Sanborn Library has been searched by EDR and maps covering the target property location as provided by GEI Consultants Inc. were identified for the years listed below. The Sanborn Library is the largest, most complete collection of fire insurance maps. The collection includes maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow, and others. Only Environmental Data Resources Inc. (EDR) is authorized to grant rights for commercial reproduction of maps by the Sanborn Library LLC, the copyright holder for the collection. Results can be authenticated by visiting www.edrnet.com/sanborn.

The Sanborn Library is continually enhanced with newly identified map archives. This report accesses all maps in the collection as of the day this report was generated.

Certified Sanborn Results:
